# What is a Nordic Swan Ecolabel Floor covering and flooring underlay?

Nordic Swan Ecolabel floor coverings and flooring underlays have a reduced environmental impact as they contain a high share of responsibly sourced renewable and/or recycled materials, saving resources. Moreover, the production must be energy efficient to decrease its effect on the climate.

To be resource efficient, the products must demonstrate good quality performance and a long service life. To minimize the product's impact on health, strict requirements are set on the chemicals used in production and on emissions released to the indoor environment. Finally, requirements on quality, traceability, reparability and recyclability help promote circular economy.

A Nordic Swan Ecolabel floor covering or flooring underlay:

- Is made of a high share of renewable and/or recycled materials.
- Has responsibly sourced renewable raw materials, through requirements for traceability and a high share of certified wood raw material.
- Comply with tough requirements relating to chemicals that are harmful to environment and/or health, including a ban on phthalates, halogenated flame retardants, PFAS and identified and potential endocrine disruptors on up-to-date lists from EU and national authorities.
- Meets ambitious requirements for energy efficient manufacturing, an important contribution to reduced climate impact.
- Meets requirements for emissions of formaldehyde and VOC to ensure a safe indoor environment.
- Is quality and performance tested and verified to guarantee a long lifespan. A 5-year warranty must be provided.
- Is traceable to the manufacturer to ensure reparability and/or recyclability.
- Fulfills all requirements for materials in Nordic Swan Ecolabel new buildings and renovations.

## 1 Summary

The Nordic Swan Ecolabel criteria for floor coverings and flooring underlays have been revised and updated to generation 7. The structure of the criteria has been changed and textile floor coverings have been moved to a new separate criteria document. This type of product is, therefore, not part of the revision. Flooring underlays have been added to the criteria's scope, hence the change of name.

Nordic Swan Ecolabel Floor coverings and flooring underlays have reduced environmental impact as they must contain a high share of sustainably sourced

renewable materials or, a high share of recycled materials, or combination of thereof, allowing natural resources savings. Moreover, the production of Nordic Swan Ecolabelled Floor coverings and flooring underlays must be performed in an energy-efficient way decreasing their contribution to climate change. Nordic Swan Ecolabel Floor coverings and flooring underlays have good performance and a long service life which further decreases the need of extracting/harvesting raw materials. To minimize the product's health strict requirements are set on the chemicals used during their production and on the level of emissions released to the indoor environment. Finally, requirements set on chemicals contained in recycled materials as well as requirements on traceability, reparability and recyclability make the products more aligned with the concept of circular economy.

### **Updated material requirements**

The extraction of renewable can have major effects on the environment, especially on biodiversity and on landscapes. The requirement on the use of certified virgin renewable materials and documented recycled materials has been tightened in the draft of the new criteria. New requirement has been introduced for responsible sourcing of renewable materials used in the production of polymers contained in plastic, rubber and foam materials. At the same time, the requirements for minimum share of renewable materials or, share of recycled materials, or combination of thereof has been tightened.

### **Updated chemical requirements**

The requirements on the production chemicals have also been tightened as the vast majority of substances classified as CMR are excluded. Furthermore, a number of substances or group of substances have been added to the list of forbidden substances and must neither be used in chemical products nor as additives in materials (notably, endocrine disruptors and PFAS). Finally, to ensure that the products contribute to a safe indoor environment, the requirement on emissions of VOC, SVOC, formaldehyde as well as CMRs (category 1A and 1B) has been tightened and updated to match the draft published by the European Commission on EU Taxonomy.

### **Updated energy requirements**

Overall reduced energy consumption, the use of renewable sources and energy-efficient production are important parameters to reduce the emission of greenhouse gases, highly contributing to climate change. Therefore, a requirement on energy management has been implemented and the energy consumption requirement has been tightened. Moreover, the energy consumed for several additional processes occurring during manufacture must be now included in the calculation of the latter. Finally, the production of raw materials uses also significant quantities of natural resources. That is why, the energy consumption requirement covers also the energy consumed during manufacture of the main binders in plastic and hybrid floorings.

### **Updated circular requirements**

Several requirements have also been either updated or added to increase the circularity of Nordic Ecolabelled floor covering and flooring underlays. The quality and durability requirements, ensuring that the products have a long

service life, and the product information requirement, making sure that all relevant information on how to extend the service life or how to handle the products once they have reached their end-of-use, have been updated. Requirements on products traceability, reparability and recyclability have been added to help manufacturers setting in place the first processes before having a fully operational take back system. Furthermore, strict chemicals requirements set on recycled materials contained in the products and a requirement on packaging, also contribute to eliminate the concept of waste, one of the pillars of circular economy.

### **Changes compared to previous generation**

As in the previous version of the criteria, Nordic Swan Ecolabelled products must meet the requirements of the Construction Products Regulation (EU/305/2011) in relation to the documentation of the properties and functions with which the product is marketed. New in the criteria is a set of requirements entitled “Innovation requirements” and having for purpose to reward manufacturers that have come further in their sustainability work, and especially further that Nordic Ecolabelling’s requirement in some areas or phases of the products’ life cycle.

For a full description of the changes in the revised generation 7, see the table in chapter 6.

### **Nordic Swan Ecolabelled floor coverings and flooring underlays**

Nordic Swan Ecolabelled Floor coverings and flooring underlays have reduced environmental impact as they must contain a high share of sustainably sourced renewable materials and/or a high share of recycled materials, allowing natural resources savings. Moreover, the production of Nordic Swan Ecolabelled Floor coverings and flooring underlays must be performed in an energy-efficient way decreasing their contribution to climate change. The products have good performance and a long service life which further decreases the need of extracting/harvesting raw materials. To minimize the product’s health impact, strict requirements are set on the chemicals used during their production and on the level of emissions released to the indoor environment. Finally, requirements on products traceability, reparability and recyclability make the products more aligned with the concept of circular economy.

A Nordic Swan Ecolabelled floor covering or flooring underlay means:

- The products must contain a high share of renewable and/or recycled materials.
- Installation waste of linoleum and plastic flooring must be recycled. Products other than wood floor coverings must be recyclable.
- Reparability for all floor coverings must be ensured. Traceability between not glue down products and the manufacturer must be guaranteed.
- The renewable raw materials must be sustainably sourced, through requirements for traceability and a high share of certified wood raw material must be guaranteed.

- Chemicals used in production such adhesives and surface treatments must have a good environmental and health profile. For instance, endocrine disruptors, phthalates, halogenated flame retardants and PFAS must not be added to the products.
- The manufacturer must work continuously on an energy optimisation strategy and the product must be manufactured in an energy efficient way.
- Emissions of formaldehyde and VOC from relevant chemicals, from the final product must be low to ensure a safe indoor environment.
- The product's quality and performance must be tested so it can fulfil its function through its long service life. A 5-years warranty must be provided.
- Fulfil all requirements for materials in the criteria for Swan labelling of buildings and renovations.

## 2 Environmental impact of Floor coverings and flooring underlays

The criteria include very heterogenous products in terms of materials as they cover, among others, wooden flooring, bamboo flooring, linoleum flooring, laminate flooring and plastic flooring. The same remark can be made regarding underlays, which is the newly included product type covered by the 7<sup>th</sup> generation of the criteria.

Despite the differences between the used materials, the main environmental impact of floor coverings and underlays are the same for all types and comes from the extraction/cultivation and the production of the materials themselves;<sup>1</sup> that is, mainly, wood-based materials, linoleum and plastics/polymers.<sup>2</sup> However, floor coverings and underlays of good quality/materials have longer lifespan, decreasing the contribution that the raw material stage has in the product's overall environmental impact. Consequently, the impacts from the use stage becomes more significant, making the basis for good indoor climate (low emissions) and, for instance, the use of recommended cleaning and maintenance methods crucial aspects.<sup>3</sup>

Resource use, chemicals hazardous to the health and the environment, energy consumption, carbon footprint and biodiversity loss have all been identified as direct environmental impacts associated with this product group. Production of floor coverings is an energy-intensive process and is linked to the emissions of substances that are harmful to health and the environment, as adhesives may be required in the construction of the products and the application of a surface treatment is performed. The use of recycled materials has a direct positive effect as it reduces the quantity of virgin materials and flooring/underlays produced. To a higher extent, the same claim can be made if used floor coverings/underlays are

<sup>2</sup> Feasibility study of wall and floor coverings with a view to establishing EU eco-labelling criteria, 2000

<sup>3</sup> Jönsson, Å. Including the use phase in LCA of Flooring Coverings, 1999

recovered, reused and recycled instead of being incinerated, which remains their prevalent way of disposal in the Nordic countries. Environmental costly resources can be spared, and material loops kept tight. Ensuring that both recycling fractions and virgin materials used in the manufacturing of the floor covering/underlays do not contain any harmful chemicals is key to promote recycling and further reducing the product's environmental impact in all stages.

See more details regarding the environmental impact of floor coverings/underlays in the MECO and RPS analyses. The purpose of the analyses has not been to rank the different flooring types or underlays materials in relation to each other, but instead to define the important environmental parameters for the different types of products. More details about the contribution of Nordic Swan Ecolabelled floor coverings and flooring underlays to circular economy can be found in the section bearing the same name. Likewise, more information on how these criteria can help opposing climate change and biodiversity loss is given in the next sections. Finally, the section UN Sustainable Development Goals shows how Nordic Swan Ecolabelled floor coverings can related to the various goals.

## 2.1 Qualitative MECO analysis

The relevant environmental impacts found in the life cycle of each of the flooring types (e.g., wooden, bamboo, linoleum and plastic) and flooring underlays types are set out in the qualitative MECO table below. A MECO describes the key areas that have impact on the environment and health throughout the life cycle of the product – including consumption of materials/resources (M), energy (E), chemicals (C) and other impact areas (O).

A relevant functional unit would be 1 m<sup>2</sup> flooring, with the possibility to include underlays, for an average product lifetime of 20 years, including installation and maintenance. But because of the lack of recent and harmonised data from LCA studies for all materials, it has not been possible to perform a full quantitative MECO analysis. Furthermore, very different materials and combinations thereof can be used in a floor covering or underlays. That is why, it has been assessed that a qualitative MECO is better suited for that particular product group.

The performed MECO analysis is made for floor coverings and flooring underlays included in the product group definition.

Qualitative MECO matrix for the life cycle of floor coverings and underlays.

	Raw material stage	Production	Use stage	End-of-use stage
<b>Raw materials/ inputs</b>	Wooden floors (solid wood, parquet, laminate, cork and bamboo floorings) and corkment underlays: Land use through deforestation, use of primary raw materials (wood, wooden panels, cork bark and bamboo). Use of endangered tree species. Seldom use of secondary raw materials in the manufacture of wood flooring or HDF included in laminate floorings.	Recycled/reused raw materials can be used in the manufacture of plastic and wooden flooring.  Energy resources for production.  Emissions to air and water during production.	Adhesives to install the flooring. Underlayment to improve the performance of the flooring. Refurbish with new surface treatment) (maintenance).  Floor coverings have a long lifespan. The thickness of the wooden floor's top	Worn out floorings and underlays are mostly incinerated (energy recovery) in the Nordic countries. However, possibilities to reuse wood from solid wood flooring exist.  Possibility for material recycling for laminate flooring, plastic and linoleum floorings (production waste,

### Summary of the most important environmental impacts found in the MECO analysis

The hotspots, or stages and processes in the product's life cycle that have a high environmental impact, identified during the MECO analysis can be found below.

#### *The raw material stage:*

Raw materials can be either of renewable sources or are of fossil origin. Wood is the most used material and is included in the manufacture of solid wood, parquet and wood-based panels (part of a laminate flooring). However, other plant-based materials are also widely employed as they are the main ingredients in linoleum, cork and bamboo flooring and corkment underlays. Bio-based/bio-attributed plastics, and even bioplastics (where the building blocks themselves come directly from fermentation or other natural process) can also be used. Production of the necessary renewable materials have a significant impact on the environment. Indeed, loss of biodiversity through using endangered tree species as well as through deforestation and land use are direct consequences.

Plastics of fossil origin are though much often used as they are more available and consequently cheaper. Secondary raw materials such as recycled plastics and materials can also be found in floor coverings and flooring underlays. Recycled plastics and especially polyolefins can be used as raw materials while post-production and pre-consumer recycling flooring material can re-enter the manufacturing process with the help of waste minimising actions or take-back systems. However, secondary wood-based raw materials, such as wood chips in HDF or reused wood, are rather used for their energy content (incineration for energy recovery or biogas production) than contained in laminate or solid wood flooring respectively.

Chemicals used during the manufacturing of flooring are usually of fossil origins. Though, natural adhesives made from organic sources are becoming more available. Many different chemicals and chemical products must be manufactured and be used in the production of floor covering and underlays. Adhesives, fillers, resins, accelerators and other additives, as well as surface treatments give the material or the final product its desired properties.

Consumption of various energy raw materials has also been linked to both the raw material and the production stages. There are no specific energy raw materials here that should be highlighted, as it will depend on the available energy sources where the processes take place. The quantity of water used to produce the different raw materials, especially those coming from renewable sources, is also an important aspect to consider.

*The production stage:*

The main environmental impacts caused in this life cycle stage are due to the energy consumption in the manufacturing stage of floor coverings and flooring underlays.

Regarding wooden floorings, there are a certain number of common steps in every production process such as drying and sawing that are considered high energy intensive processes. The freshly produced and calendared Linoleum must also be stored and dried until it has fully cured. The manufacture of plastic flooring requires that ingredients are firstly extruded to produce a malleable material. The material is then calendared and pressed to obtain its desired shape and characteristics. Energy consumption for the application of surface treatment, the production of chemicals, raw materials and bought-out parts (e.g., HDF and backing layer) used in the manufacturing of flooring can also be of significance.

The production stage is also where most of the harmful emissions take place and generate a non-negligible amount of waste. Especially in the case of the production of MDF/HDF (included in laminate and other hybrid floorings) that causes emissions of total particulate matter/dust from dryers, consisting of wood dust and condensable organic compounds and emissions of non-condensable natural VOC, including formaldehyde. Another source of VOC/SVOC and harmful chemicals to health and the environment is the application of a surface treatment or finish at the end of the flooring manufacturing process.

*The use stage:*

As the raw material and production stages have high environmental impacts, it is important that the materials used are of good quality and that the floor covering, or flooring underlays has a long lifespan. The floor covering must perform accordingly to the requirements stated by the area of use so its service life can at least be 20 years. The use of underlays can extend the floor covering's service life as well as improve the user experience (e.g., sound dampening, walking comfort).

Loose-laid flooring or floorings installed without the use of adhesives, have the advantage to be more easily repairable. Floor coverings based on click-systems allow the user to change the damage plank or tile more easily.

Installing a floor can be physically demanding for the workers and it is important to choose adhesives that can both perform in the best way possible and have good health and environmental profile. Furthermore, the longer the service life is, the higher the contribution from the use phase from a product's life cycle becomes in relation to its overall health and environmental impacts. That is why adhesive, formaldehyde-based resins/glues, surface treatments as well as the materials the flooring is made of must be chosen so they do not negatively affect indoor environment by releasing too much VOC/SVOC.

A long service life means more chemicals used for cleaning and maintenance over the years. At the same time, it is worth noticing that certain chemicals and machines used for cleaning can contribute to the release of microplastics. Finally, antibacterial substances or nanomaterials from surface treatments as well as

various plastic additives can potentially migrate from the product to the indoor environment.

*The end-of-use stage:*

Loose-laid or adhesive-free installed floorings can be designed for repair and damage tiles or planks can be easily replaced, making the products overall more circular. In the case of glued-down flooring, the type and quantity of adhesive may hinder treatment of old flooring and consequently material recycling and recirculation.

Wood, linoleum and plastic flooring can be sanded, and a new coating can be applied afterwards. Refurbishment/renovation/repair/reuse are processes with low environmental impact and should be promoted and preferred over material recycling and of course production of new virgin material and product.

All the materials used for manufacturing floor coverings and flooring underlays are characterized by having high energy content and/or being considered as CO<sub>2</sub> storage. Landfilling or incineration without energy recovery must be prevented, also because of the emissions/migration of chemicals occurring during these processes.

Recycling uses less energy than that required to manufacture virgin materials. The use of reused/recycled raw materials reduce drastically the overall resource consumption associated to floor coverings/underlays manufacturing. Reused wood, recycled plastics, recycled wood-based materials can re-enter the manufacturing process and be used instead of virgin materials. That is why, it is of uttermost importance that the recycled fractions are of good quality and do not contain undesirable or legacy chemicals as remains from previous material uses.

Waste generated during manufacturing can either be used because of its high energy content (wood-based waste can be used as fuel in combustion plants) or be reused as input in the process (post-production waste in plastic and linoleum flooring production). Pre-consumer or post-installation waste (10% of the flooring becomes scraps during installation<sup>4</sup>) can also be reused instead of virgin materials and become new flooring. Post-consumer flooring/underlays material is still scarcely used as input in the manufacturing of new products as many parameters must be considered. As of today, and for compatibility reasons, flooring manufacturers are able to reuse in the production of new floor coverings only post-consumer recycled flooring material that they selves manufactured in the first place; hence the current need for manufacturer-specific take-back system over systems managed by industry associations.

To ensure flooring and underlays manufacturers the access to post-consumer recycled material of good quality and purity, actions can be taken to put a take-back system in place. The way to a fully operational take-back system includes several steps, each of them being associated with issues. These issues are responsible for the relatively low manufacturers' steerability in managing to recover their own products once they have reached their end-of-use. However, some of these issues can be addressed by the manufacturers so that the chance the product finds its way back increases, no matter the number of actors involved

---

<sup>4</sup> <https://www.golvbranschen.se/miljo-hallbarhet/golvatervinning-for-installationsspill/>

along its service life. For instance, working with materials that are recyclable and developing in-house processes enabling recycling of these could be seen as a first important pillar. As a matter of fact, flooring comprising many different materials, as for instance laminate flooring, are much more difficult to recycle compared to floorings of more homogeneous composition (e.g., plastic and linoleum floorings).

## 2.2 RPS analysis

Nordic Ecolabelling sets requirements on the stages and processes in the product's life cycle that have a high environmental impact – also called hotspots. A tool called RPS is used to identify where ecolabelling can have the greatest impact. R stands for relevance and identifies the environmental issues; P stands for potential and lists the area where the product's environmental impact can be reduced, and S is for steerability, meaning the possibility to set requirements that can be documented and followed up.

The objective of Nordic Ecolabelling is to steer the industry towards the environmentally best flooring or underlays within each of the different product or material types. That is why, it has been assessed that requirements can be set at the different stages of a floor coverings or flooring underlays' life cycle and environmental gain can be achieved by fulfilling all criteria, no matter the materials used. The table below provides an overview of the key areas where requirements are pertinent, beneficial and applicable due to a high or medium RPS.

**Table 1: Summary of results of the RPS analysis.**

Lifecycle stages	Area and assessment of R, P, S (high, medium or low)	Comments
<b>Raw materials</b>		
Wooden floors (wood, bamboo, cork and laminate floorings, as well as engineered wood floorings, design wood floorings and hybrid floorings containing high proportion of wood-based materials) and underlays made mostly of wood-based materials.	<b>Resources – wood raw materials</b> R: High P: High S: High	Wood raw materials used in floorings have a high RPS.  From a life cycle perspective, forestry is a key part of wood products' environmental impact, and it is also important that wood as a renewable raw material is grown / harvested and used in a sustainable way.  Much of the world's forest loss is driven by conversion of natural forest to other land uses such as cattle farming, palm oil and soy plantations. Deforestation and degradation from illegal and unsustainable logging, fires and fuelwood harvesting can harm wildlife, jeopardize people's livelihoods and intensify climate change.  Credible forest management certification contributes to a more sustainable wood / timber product industry by helping create market conditions that support forest conservation. Requirements for high share of certified wood raw materials and certified traceability ensures more sustainable forestry.
Linoleum floors, Hybrid flooring and underlays containing other raw materials than the most common ones.	<b>Resources – other raw materials</b> R: High P: Medium S: Medium/Low	The individual plant used to produce the natural fibre, or any other renewable raw material must be obtained in the least environmentally impactful way. However, the products in this product group are expected to include relatively low amount of textile fibres.  Only flax and other bast fibres are expected to be extensively represented in flooring because of their use in linoleum floorings. That is why, specific requirements

		<p>on biocides use and on COD/TOC values have been specifically set.</p> <p>The supply chain being very long from the cultivation to the production of the final flooring and the relatively low impact of the fibre types used in this product group are responsible for the medium potential and low steerability.</p> <p>Furthermore, a multitude of raw materials can be used in hybrid floorings or underlays. Hence, it is required that other raw materials may be used only if they are residual products from processes or 100% pre/post-recycled material. Full traceability must be guaranteed.</p>
Plastic floorings, floorings containing WPC, floorings containing rubber and/or foam materials and plastic-based underlays	<p><b>Resources – Virgin fossil plastic raw materials and plastics produced from renewable raw materials</b></p> <p>R: High P: High S: High</p>	<p>The production of plastics and polymers is highly energy and resource demanding. However, it is troublesome to obtain relevant energy consumption and other resource consumption related to the production of specific plastic/polymer types. Instead, a requirement is set demanding that plastic flooring/underlays must contain a high share of recycled and/or renewable materials.</p> <p>Additional requirements are set on the additives added to the plastic/polymer material as it is known that some of them are classified as hazardous which may affect indoor environment under the use phase and hampers the recirculation/recycling of the material once the product has reached its end of life.</p> <p>Regarding, bio-based plastics/polymers used in underlays/floorings, requirements may be set depending on the raw material used. Plastics/polymers produced from of waste or residual products defined in accordance with (EU) Renewable Energy Directive 2018/2001 are preferred over virgin bio-based plastics and obviously virgin fossil-based plastics and polymers.</p> <p>Specific requirements on composite material have been set to minimise the material environmental impact and to ensure that composite-containing floorings meet the most stringent limit values.</p>
All flooring types	<p><b>Resources - recycled raw materials</b></p> <p>R: High P: Medium/High S: Medium/High</p>	<p>Use of recovered and recycled materials such as renewable fibres/materials, plastics or even flooring materials will reduce the negative environmental impact of all types of underlays/floorings.</p> <p>Requirements that linoleum, plastic and other type of floorings except wood-based floorings must contain recycled materials will reduce the need for virgin raw materials and thus save natural resources. The potential for using recycled materials is relatively low in wood-based products, often because of how a flooring product is constructed/produced but also because wood may be requested by the energy sector.</p> <p>A challenge of using recycled materials can be the content of harmful substances. Recycled wood raw materials therefor need to be tested to reduce the spread of substances of concern and promote the potential of material reuse in the future. The traceability for recycled wood materials is high due to widespread certification schemes.</p> <p>Recycled polymers/plastics, foam and rubber as well as recycled leather and fibres must also be tested for hazardous chemicals deemed as most relevant for this product group.</p>
<b>Floorings and underlays production</b>		
All product types	<p><b>Energy - Production</b></p> <p>R: High</p>	High RPS has been identified for energy consumption and its contribution to climate change during the production of floorings and underlays. Working on having

	<p>P: High S: High</p>	<p>a more energy-efficient production, reducing overall energy consumption and increasing the use of renewable energy and fuel play an important role in minimising the product's overall environmental impact.</p> <p>Energy consumption during production of the materials necessary in the product's construction has also been identified as having high RPS. This concerns wood-layers, plastic binders, HDF, linoleum cement and any other main material used in the product.</p> <p>Both energy consumption during the production of the final product and during the production of materials are included in a requirement with limit values that shall not be exceeded.</p> <p>However, steerability to reduce energy consumption for producing chemicals used during the manufacture of floorings and underlays (e.g., adhesives and surface treatments) was identified as low. This, because of the lack of data and the high number of different chemicals that may be used. That is why, it has been left out from the energy consumption requirement.</p>
All product types	<p><b>Waste - Production</b> R: Medium P: Medium S: Medium</p>	<p>Minimization waste production ensures an efficient use of resources (energy and material), enables resource savings and contributes to increase the circularity of the product.</p> <p>Wood dust is produced during the manufacture of wood-based flooring that can be used as renewable fuel. The production of linoleum and plastic flooring generates waste that can re-enter the process and become new floorings.</p> <p>A requirement is set so that all production waste must be either energy recovered or reused and reprocessed according to the good practices. Such requirement can be met easier if a waste minimization management programme is implemented.</p>
All product types	<p><b>Chemicals - Production</b> R: High P: High S: High</p>	<p>Reducing the quantity of health and environmental harmful chemicals and substances used during the production of floorings and underlays has high RPS. However, steerability lowers once one gets further away from the manufacture of the main raw materials and of the final product.</p> <p>SVHC, substances assessed as PBT/vPvB and/or listed as endocrine disruptors can be found in various chemical products. Chemical products such as adhesives, resins and surface treatments can be a source of phthalates, PFAS, chlorinated paraffins biocides, nanomaterials and VOCs such as formaldehyde, among others. Requirements can be set so that a wide range of hazardous substances is excluded, does not migrate or is emitted during the use phase, and does not pollute or contaminate during the end-of-life phase. For instance, application technologies leading to the least VOC emissions are encouraged.</p> <p>Potential and steerability also exist for requirements set at the production stage to limit emissions to air and water. Especially in the case of laminate floors manufacturing. These requirements ensure that both end-users and workers are exposed to as little harmful chemicals as possible.</p>
All product types	<p><b>Packaging</b> R: Medium/Low P: High S: Medium</p>	<p>There is a relevance for plastic material used as packaging as they are produced from fossil feedstock. There is also relevance for paper and cardboard packaging as their production from wood fibres leads to deforestation and biodiversity loss.</p>

		Requirement is set to promote the use of recyclable packaging/material to further reduce the products' environmental impact.
<b>Use stage</b>		
All product types	<b>Chemicals – Emissions</b> R: High P: High S: High	<p>An overall high RPS has been found to set requirements on the emissions generated by the finished flooring and underlays.</p> <p>High indoor environment quality is very important from the consumer's point of view and that means that they must be protected from emissions of VOCs and CMRs substances, such as formaldehyde.</p> <p>Steerability lowers regarding chemicals used for installation, maintenance and cleaning. Adhesives, oil, levelling compounds and waxes (sometimes containing microplastics) must often be used. Manufacturers can only give recommendations on what chemicals should be used.</p>
All product types	<b>Quality and durability</b> R: High P: High S: Medium	<p>A high relevance and potential have been found to set requirements on the quality and durability of the floor covering. The longer the service life for a floor covering is, the less its environmental impact becomes. The consumption of chemicals, raw materials and energy is drastically reduced.</p> <p>High steerability is illustrated by the numerous continuously updated quality and durability standards/technical bulletins specific to the materials or type of flooring/underlays. These must be met to ensure that the product has a long lifespan.</p> <p>Once, the product has been installed, steerability gets lower. However, Information intended to extend the product service may be provided by the manufacturer and made easily available for flooring installers, consumer and cleaning services.</p>
<b>End-of-use stage</b>		
All flooring types	<b>Circularity/recyclability – take-back systems</b> R: High P: High S: Low	<p>High relevance and potential have been identified regarding setting requirements at the end-of-use stage to increase recycling of floorings and decrease their incineration. Steerability is however hampered by many parameters such as the choice of the material used in the floorings and their recyclability, the long service life of floorings and the lack of traceability between the installed products and the flooring manufacturers, as well as the numerous actors involved in the life cycle of floorings and the lack of communication between them. As a result, no flooring manufacturers have a fully operational take-back system for worn out floorings as of today.</p> <p>However, Flooring manufacturers have steerability in some cases:</p> <ul style="list-style-type: none"> <li>- Labelling and traceability can be ensured for some flooring types and in some product areas.</li> <li>- The choice of materials or installation (e.g., with or without adhesive) can facilitate recover and recycling of the floorings.</li> <li>- The services offered can be communicated to the customers.</li> </ul> <p>A requirement is set to ensure that all flooring manufacturers develop technologies enabling recycling of all their products, except for wood floorings. They must also offer to recover installation waste for their plastic and linoleum floor coverings.</p> <p>A requirement is set on product and consumer information stating that all services offered by the</p>

		<p>manufacturer with purpose to proper handle the product when it has reached its end-of-life must be communicated.</p> <p>Because steerability towards a fully operational take back system for used floor coverings is low to medium, it is also required that the products contain a high share of renewable and/or recycled materials to reduce its overall environmental impact.</p>
All flooring types	<p><b>Reuse, Renovate and Repair</b></p> <p>R: High P: High S: Medium/Low</p>	<p>High relevance and potential have been identified regarding setting requirements at the end-of-use stage to increase reuse, repair and renovate of floor coverings. These processes have the most beneficial benefits as they lead to the least depletion of natural resources, contribute less to climate change and generate less waste.</p> <p>To promote reuse and repair, requirements are set on the possibility to renovate/refurbish the flooring and on the possibility of disassembly and replace if the flooring can be installed without the use of permanent adhesives. Furthermore, a requirement on warranty ensures that the product must be repairable though out its service life. Once again, the product information requirement guarantees that all possibilities are communicated to the end-user.</p> <p>Finally, to increase the chance for renovate/repair, it is required that a maintenance plan is provided with the purchase of a floor covering. Hence, actions to renovate/repair the flooring can be planned with the different actors involved.</p> <p>Unfortunately, steerability remains low to medium as it is still up to the end-user to do the right thing and take actions to reuse/renovate/repair the product instead of buying anew.</p>

## 2.3 Circular economy and Climate

The Nordic Swan Ecolabel is a good tool for companies working on adjusting their business models (and/or products) and willing to make the shift towards a more circular economy. Indeed, the entire product life cycle, including the phases known as raw materials extraction, production, use and end-of-use (e.g., the 3 different scenarios, landfilling, incineration and recycling are considered) is scrutinised. This holistic approach enables the drawing of a bigger picture where all material loops involved in the manufacture of a product are considered. This step is crucial to pinpoint the areas or processes needing adjustments or corrections to be more in line with the concept of circular economy. These so-called hot spots related to circular economy may then serve as basis for the development of circular requirements found in a specific product group's criteria. More information about how the Nordic Swan Ecolabel generally contributes to a circular economy can be found on our website.

Actions taken to commit to the shift towards a more circular economy (through rendering the products more circular) are often closely related to actions taken to reduce the products' contribution to climate change. Therefore, requirements on Nordic Ecolabelling floor coverings and flooring underlays associated with these two aspects are described together below:

- The criteria promote sustainable forestry, protecting key habitats for biodiversity. Forest areas are known to play a role in regulating the climate.

- The criteria promote the use of sustainably harvested renewable materials as well as the use of pre-/post-consumer recycled materials of good quality and purity. This leads to a lesser need of using natural resources (e.g., energy, chemicals, materials and water) and especially a lesser need of extracting more oil to produce virgin fossil materials, highly contributor to climate change.
- The criteria promote the use of chemicals of less environmental and health impact and the production of materials, floor coverings and flooring underlays which do not contain the most hazardous substances. This allows recycling of the materials without the risk of recirculating, for instance, hazardous additives in plastics fractions. Furthermore, a specific requirement is set on recycled plastics so that they are not contaminated with, for example, halogenated flame retardants and heavy metals.
- The criteria promote the use of renewable fuel and energy sources. The energy management and consumption requirements are set so that the manufacturers work continuously on reducing their CO<sub>2</sub>-emissions and consequently their general climate impact, as well as on manufacturing specific products in a more resource-efficient fashion. Furthermore, requirements on waste management and on recyclability have for purpose to promote recover/recycling of the waste generated during manufacture. As previously stated, the use of recycled materials further reduces the overall energy consumption and thus, the product's climate impact.
- The criteria promote products with long service life through requirements on quality and durability as well as on product/consumer information. Raw material extraction and product manufacture being the most environmental impactful steps, it is of uttermost importance that Nordic Ecolabelled products have a long service life.
- The criteria promote reuse/repair/renovate of floor coverings over the purchase of new products when this can be avoided. Requirements on reparability and warranty as well as on traceability and maintenance are part of an attempt to tackle overconsumption and reduce the product environmental impact.
- The criteria promote the development of a take back system. A take back system enables recycling of flooring materials and decrease drastically the need for production of new chemicals and materials and the overall need for resources employed during manufacture. Requirements on traceability and recyclability are set to increase the chance of recycling worn out floorings.

## 2.4 Biodiversity

Biodiversity is the variability of all living organisms on Earth and how they interact. Biodiversity or biological diversity is the variety and variability of life on Earth. Biodiversity is a measure of variation at the genetic (genetic variability),

species (species diversity), and ecosystem (ecosystem diversity) level.<sup>5</sup> Biodiversity plays an important role and is beneficial for society,<sup>6</sup> as demonstrated by the development of ecosystem services. These come in three flavours:

- Provisioning services which involve the production of renewable resources (e.g.: food, wood, fresh water),
- Regulating services which are those that lessen environmental change (e.g.: climate regulation, pest/disease control) and,
- Cultural services represent human value and enjoyment (e.g.: landscape aesthetics, cultural heritage, outdoor recreation and spiritual significance).<sup>7</sup>

In 2019 the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES) published its first global report, calling for transformative change. The world must bring biodiversity back into the production landscapes in addition to creating more protected areas. In 2022 the UN Convention on Biological Diversity<sup>8</sup> adopted the Kunming-Montreal Global Biodiversity Framework agreeing to conserve and manage at least 30 percent of the world's lands, inland waters, coastal areas and oceans.

Nordic Ecolabelling contributes to protect biodiversity by requiring that renewable raw materials are sustainably sourced and by promoting the use of waste/residues or recycled materials instead of virgin raw materials, thus, enabling natural resources savings. The goal is to counteract loss of species and deterioration of ecosystems, and that sourcing of biological raw materials is in balance with regeneration.

## 2.5 UN Sustainable Development Goals

Of all UN sustainable development goals, the one that the Nordic Swan Ecolabel contributes the most to is Goal 12, “Ensure sustainable consumption and production patterns”. Through setting requirements at the different phases of the lifecycle and especially on resource use, as well as on the chemicals and the materials included, the Nordic Swan Ecolabel commits to reduce the environmental impact associated with the production and consumption of goods. The same requirements enable control of the supply chain, ensures sustainable production and leads to the delivery of sustainable products to the end-user. The end-user can then safely use the products throughout their service life.

Nordic Swan Ecolabelled products are manufactured all over the world. Wherever the Nordic Swan Ecolabelled product is made, its manufacture must fulfil strict environmental requirements that go beyond the legislation in place. This promotes more environmentally-friendly production methods – in

<sup>8</sup> <https://www.unep.org/un-biodiversity-conference-cop-15>

developing countries too. The criteria for floor coverings and flooring underlays contribute to Goal 12 as follows:

- Requirements on the share of renewable and/or recycled raw materials. Especially requirements for certified sustainable wood raw material and their traceability. These requirements are for purpose to lower the product's overall environmental impact and consequently contribute to more sustainable production.
- Requirements on energy management and energy consumption during the products' manufacture. These requirements are directly linked to sustainable production.
- Requirements on harmful chemicals to health and to the environment reduce the emissions of undesirable substances during production, use and end-of-use phases, at the same time facilitating potential material recovery in the future.
- Requirements on quality, durability and product information to ensure long service life. These requirements enable efficient use of natural resources.
- Requirements on traceability, reparability and recyclability may further reduce the environmental impact associated to production and can drastically contribute to a more sustainable consumption.

Although Nordic Ecolabelling mainly contributes to Goal 12, Target 3.9 may also be addressed. Target 3.9 focuses on mortality due to environmental pollution. Comprehensive and strict requirements on chemicals all contribute to this target.

## 3 Other labelling schemes and management systems

### 3.1 EU Taxonomy

There are still some uncertainties on how EU Taxonomy compliance can be documented as well as interpreted. Therefore, Nordic Ecolabelling cannot guarantee alignment between EU Taxonomy's requirements and its requirements on Floor coverings and flooring underlays yet. Nordic Ecolabelling does not take any legal responsibility for the (degree of) alignment, nor can a Nordic Swan Ecolabel building material (or listed in the Supply Chain Declaration Portal) be claimed as taxonomy aligned based on the ecolabelling criteria. The responsibility for documentation of EU taxonomy compliance solely belongs to the company who is claiming it. Nordic Ecolabelling closely follow interpretations of the EU Taxonomy criteria in both the Nordic countries and from EU. In the end the interpretation is a task for national authorities or other officially appointed bodies.

However, when it comes the Delegated Act on the objective climate change mitigation (Commission Delegated Regulation (EU) 2021/2139 of 4 June 2021) the following issues have been handled in the criteria for Floor coverings and flooring underlays. Specifically, reference is made to the activity 7.1 "Construction of new buildings: 7.1.5.2: Pollution and prevention control", i.e.,

*Building components and materials used in the construction that may come into contact with occupiers emit less than 0,06 mg of formaldehyde per m<sup>3</sup> of test chamber air upon testing in accordance with the conditions specified in Annex XVII to Regulation (EC) No 1907/2006 and less than 0,001 mg of other categories 1A and 1B carcinogenic volatile organic compounds per m<sup>3</sup> of test chamber air, upon testing in accordance with CEN/EN 16516 or ISO 16000-3:2011 or other equivalent standardised test conditions and determination methods.*

This requirement is relevant for the criteria for Floor coverings and flooring underlays. The proposed requirement for formaldehyde emissions is harmonised with the EU Taxonomy requirement. Nordic Swan Ecolabelling is aware that the specified test conditions referred to in Annex XVII has not yet been published. As mentioned earlier, Nordic Ecolabelling is closely following the development and interpretations of the EU Taxonomy criteria in both the Nordic countries and from EU.

### 3.2 CE marking

As of 1 July 2013, all construction products covered by a harmonised standard or European Technical Assessment (ETA) must have a performance declaration and be CE marked in order to be sold in the EU. This is regulated by the EU Construction Products Regulation (305/2011/EU), abbreviated CPR. The purpose of the Construction Products Regulation is to ensure that reliable documentation on the performance of construction products is presented in a harmonised manner throughout the EU, so facilitating free trade. Common, harmonised European standards or European assessment documents (EAD) are used to test and report the product's performance. These serve as a basis for the CE marking of the construction product. Performance requirements are set by each member state, but there are also rules on restrictions in harmonised legislation such as REACH.

The harmonised product standard, EN 14041 "Resilient, textile and laminate floor coverings – Essential characteristics" covers flooring made from plastic, linoleum, cork, rubber and textile flooring. There is an equivalent European harmonised product standard for wood flooring; EN 14342 "Wood flooring. Characteristics, evaluation of conformity and marking". This means that since 1 July 2013 these types of flooring must have a CE marking. These standards do not include flooring underlays.

It is worth noticing that the CPR is under revision and that Nordic Ecolabelling is closely following the work ongoing at the European Commission's level.

### 3.3 Other labelling schemes

#### **Type I environmental certifications**

The EU Ecolabel has criteria documents for wood-, cork and bamboo-based floor coverings (2017/176) and hard covering products (2021/476).

The German ecolabel Der Blaue Engel has criteria documents for low-emission floor coverings made of wood and wood-based materials (criteria document: DE-UZ 176), for resilient floor coverings (criteria document: DE-UZ 120), as well as for low-emission flooring underlays (criteria document DE-UZ 156).

## EPD

Environmental Product Declarations (EPD) according to the standard ISO 14025 (environmental labelling and environmental declarations Type III) have been developed with the aim of showing a product's impact on the environment from a life cycle perspective.<sup>9</sup> Different EPDs need to be based on the same PCR (product category rules), for them to be comparable to each other. A PCR describes how the calculations for an EPD should be done within a specific product area/industry. PCRs and EPDs are produced and published by so-called program operators. Program operators are often active on a national level and many countries have their own program operator.<sup>10</sup>

Product-specific EPDs ("single-company"/"product specific" EPDs) are the most common type of EPD. They are designed for a specific product from a specific manufacturer. Many flooring manufacturers have published product specific EPDs. Industry-wide EPDs ("Sector"/"Industry Average" EPDs) represent an average for a specific industry or product type. These EPDs can be based on a weighted average of data or so-called "generic" data from the industry, that is, the dominant percentage of manufacturers.<sup>11</sup> This is common in the construction industry and in the context of the EN 15804 standard, an industry wide EPD is sometimes also "Generic EPD". For instance, the trade association ERFMI (the European Resilient Floor Manufacturers Institute) has had an LCA carried out using data from ERFMI members which covered more than 85% of all European production of resilient. Output from this analysis is mainly used as input in an EPD calculator, where members can upload generic EPDs to their websites.

## Cradle to Cradle (C2C)

The Cradle-to-Cradle Certified® Products Program began as a proprietary system; however, in 2012 the certification was turned over to an independent non-profit called the Cradle-to-Cradle Products Innovation Institute. The Cradle-to-Cradle Products Innovation Institute's certification criteria from the latest version of the standard 4.0 are material health, product circularity, clean air and climate protection, water and soil stewardship and social fairness. The certification is available at several levels: bronze, silver, gold, platinum, with more stringent requirements at each. Recertification is required every three years and companies need to show measurable improvement to re-certify. Many construction products and notably floor coverings are certified according to the C2C product standard.

## FSC/PEFC – raw material labelling

The forest certification schemes Forest Stewardship Council (FSC) and Promoting Sustainable Forest Management (PEFC) play a certain role in the flooring industry. According to the manufacturers, these raw material

labels/certification schemes do not compete directly with the Nordic Ecolabel on the Nordic market.

### **Environmental certification of buildings**

There are many different systems for environmental classification of buildings used in the Nordic countries. The systems set requirements for construction materials, including flooring. For suppliers of construction materials to be included in the **LEED** (Leadership in Energy and Environmental Design) system, they must first be certified under the FloorScore system, which assesses the indoor climate performance of construction products.

The British **BREEAM** (Building Research Establishment Environmental Assessment Method) classification system requires a life cycle analysis as the basis of an Environmental Product Declaration (EPD) which is then included in BREEAM's "Green Book". BREEAM's Green Book acts as an online list of assessed products and services in the construction industry. The Norwegian version of BREEAM (**BREEAM-NOR**) sets criteria for selection of environmental hazardous substances which must not be included in construction products. In addition, emission criteria are set equivalent to the level M1 in the Finnish classification system Emission Classification of Building Materials.

The **DGNB** (German Sustainable Building Council) system in Denmark also sets environmental criteria for flooring, which includes evaluating the following substances contained: halogenated and partially halogenated fuels, heavy metals, biocides, Substances of Very High Concern and organic solvents and softeners. Level requirements are also set for the use of sustainable wood. DGNB does not set concrete emission requirements for construction materials, but does set requirements for good air quality in buildings via suitable amounts of ventilation and low emission materials. There is a focus on VOC and formaldehyde levels.

### **Assessments systems**

There are several national registration systems and environmental assessment systems for construction products and construction materials which have a major impact on the market.

- BASTA Online, based on self-registration and self-declaration followed by sample audits by an independent third party.
- Byggvarubedömningen and Sunda Hus, which are environmental assessment/environmental evaluation systems for construction materials which manufacturers sign up to.
- ECOproduct, which is both an environmental evaluation method and a database of already evaluated products. An environmental product declaration (EPD) is used as the basis for evaluating the product. ECOproduct was developed in partnership between SINTEF Byggforsk, Norsk Bygggtjeneste and NAL-Ecobox.
- There is also the electronic information system CoBuilder, which shows whether chemicals/products contain substances on the REACH Candidate List, the Norwegian priority list and BREEAM NOR's list of banned substances. CoBuilder also shows whether the products are Nordic Ecolabelled or not.

- Byggtjeneste-NOBB is another database for construction products which contains some environmental information.

## 4 Justification of the requirements

This section presents proposals for new and revised requirements and explains the background to the requirements and the chosen requirement levels. The changes carried out compared to generation 6 are listed more in details in chapter 6 Changes compared to previous version. The appendices referred to are those that appear in the criteria document "Nordic Swan Ecolabelling of Floor coverings and flooring underlays".

As previously described, the requirements written in this document are the result of an RPS analysis. The requirements are set on the steps and processes identified in the product's life cycle as having the greatest environmental impacts and where Nordic Ecolabelling has sufficient steerability to demand pertinent and credible documentation. By doing so, Nordic Ecolabelling creates good ground for differentiating between products on the market based on their environmental profile.

### 4.1 Definition of the product group

Nordic Ecolabelling has chosen to limit the criteria to floor coverings intended for indoors used as well as to flooring underlays. Flooring underlays can be defined as a thin layer of either plates or rolled material installed under the floor covering to which they may or may not be attached or glued to. The purpose of the underlays is to enhance the properties of the installation and flooring construction (e.g., levelling out subfloor irregularities, support of the flooring click system, sound dampening and humidity barrier). Floor coverings and underlays must e.g., be able to be laid on a surface of concrete or timber boarding.

Floor coverings that can be Nordic Ecolabelled are:

- wooden floorings according to EN 13756, EN 13489 and EN 14354 (solid wood flooring, multi-layer wood flooring or engineered wood floorings and wood-based panels - wood veneer floor covering/rigid floor covering),
- cork floor covering (meaning both cork tile flooring according to EN 12104 and engineered cork flooring),
- bamboo flooring,
- laminate flooring as defined in standard EN 13329.

In addition to cork flooring, the following resilient flooring can be Nordic Ecolabelled according to these criteria:

- plastic flooring,
- linoleum flooring.

Hybrid flooring, which combines wood, laminate and resilient flooring can also be Nordic Ecolabelled if the materials can fulfil all relevant requirements. However, for hybrid floorings and other flooring types containing a layer made of *recycled* composite material, specific requirements must be fulfilled (see section 4.5.5).

A Nordic Ecolabelled floor covering that is marketed and sold as flooring for wet rooms must be approved for wet rooms.

Flooring underlays, depending on the materials they consist of, are not always products covered by a harmonised standard. Hence, it is not defined exactly which types of flooring underlays can be Nordic Ecolabelled. Flooring underlays must fulfil all relevant requirements to become Nordic Ecolabelled. Flooring underlays are added to the product group definition as a separate product type and may not be certified in combination with a floor covering.

**The product group does not include the following products:**

- Floor coverings and flooring underlays which contains > 5% of a type of material not included in section 4.5 Materials. This allows floor coverings and flooring underlays to contain a limited amount of materials for which there are no requirements.
- Textile flooring. They can be Nordic Ecolabelled according to the criteria for Carpets, floor rugs and floor mats\*.
- Rubber flooring. However, it is allowed to use rubber as a material for instance in the intermediate or backing layer of the flooring.
- PVC/vinyl flooring as well as PVC as a material in flooring underlays. See requirement O5 for more information.
- Construction panels, including medium-density fibreboard (MDF) and high-density fibreboard (HDF) can be Nordic Ecolabelled according to the criteria for Panels and mouldings for interior use\*.
- Hard floor coverings based on materials such as natural stone, agglomerated stone and ceramic. These products can be certified according to the criteria from the EU Ecolabel.
- Polymeric poured seamless floors which form a hard surface upon curing.
- Flooring that is part of the load-bearing structure of the building.
- Flooring sold together with integrated underfloor heating systems.

\* See <https://www.nordic-ecolabel.org/product-groups>

Nordic Ecolabelling determines whether a product can be Nordic Swan Ecolabelled or not, and under which criteria a product can apply for a licence.

If there are other types of floor coverings or underlays being used in buildings, that are not mentioned in the product group definition above, and there is a demand for such products to be Nordic Swan Ecolabelled, an assessment may be

made as to whether these can also be included. Nordic Ecolabelling will determine which new products may be included in the product group.

### Background to the product group definition

The type of floor coverings included in the product group definition has been clarified by referring to relevant standards. Hybrid floorings may be certified if they can meet all requirements such as requirements for materials. For instance, hybrid flooring whose main material is resilient plastics must fulfil the material requirements on plastics. Recycled composite material may only be used in floor coverings and flooring underlays if they can fulfil the specific requirements set on this type of material.

The scope of the product group has also been broadened to include underlays as some of these products can contain high shares of renewable and/or recycled materials. Furthermore, because of their ability to improve the customer's experience and extend the service life of floor coverings, their use during an installation has increased. It is worth noticing that both underlays that can be laid without adhesive under floating or loose-laid installed floor coverings and those attached/glued to the floor covering can be Nordic Ecolabelled; even if this can complicate products separation and hamper material recovery/reuse. Indeed, neither the manufacturer nor Nordic Ecolabelling have the steerability to influence how the underlays is installed after being sold to the customer.

Flooring underlays are added to the product group definition as a separate product type. Indeed, the choice of flooring underlays does not depend only on the type of floor coverings installed above but also on the substrate (e.g., wood, concrete, old floor coverings) it lays on. That is why it is not feasible to certify a flooring underlay together with a specific floor covering as many different combinations of floor coverings/flooring underlays would need to be generated and some might not be even fitted for use.

Textile flooring is removed from this product group and included in the product group "Carpets, floor rugs and floor mats". Indeed, a lot of specific requirements are specifically set on this type of product, and it was deemed as more relevant to include it with other similar products mainly made of textile fibres.

Rubber floorings are still not included as it is known for a fact that they cannot fulfil the requirement on the mandatory share of renewable material, recycled material or combination of both. The use of PVC in floor covering and flooring underlays is forbidden for the reasons named in the background text of requirement O5.

## 4.2 Definitions

Words/Terms	Definitions
Bamboo flooring	Bamboo flooring means floor coverings made of bamboo in solid pieces or in agglomerates mixed with a binder. No standard definition is available yet.
CITES	Convention on International Trade in Endangered Species of Wild Fauna and Flora. CITES is an international convention for the control of trade (across borders) in wild fauna and flora at risk of extinction.
CoC	Chain of Custody – certification that ensures traceability in the supply chain.

COD	Chemical oxygen demand. A measure of how much oxygen is used during chemical degradation of organic matter.
Cork floorings	Cork floor covering means granulated cork mixed with a binder, and then cured or several layers of cork (agglomerated/veneer) can be pressed together with glue. There are two main classes of cork coverings: cork tile flooring in accordance with EN 12104 and engineered cork flooring.
Decor paper	Decor papers enable surface upgrades for wood-based substrates for use in the production of furniture, laminate flooring and other interior and exterior design panels.
Floating installation	This works with engineered, for instance, wood, laminate, cork, cork tile and bamboo floorings over a wood or concrete subfloor or existing flooring. Tongue-and-groove planks or tiles locked together mechanically. Some products are also glued together at the joints. The material generally goes over a thin foam or cork pad (known as flooring underlays), which fills minor flaws in the subfloor and absorbs sound. Installations over concrete require a thin plastic vapour barrier.
FSC	Forest Stewardship Council Certification scheme for forestry and traceability in the supply chain.
Genetically modified organisms (GMO)	An organism, with the exception of human beings, in which the genetic material has been altered in a way that does not occur naturally by mating and/or natural recombination. Within the terms of this definition: (a) genetic modification occurs at least through the use of the techniques listed in Annex I A, part 1 of the DIRECTIVE 2001/18/EC; (b) the techniques listed in Annex I A, part 2 (DIRECTIVE 2001/18/EC), are not considered to result in genetic modification.
Glued down installation	Engineered wood is typically glued. Other types of flooring can also be glued down. Adhesive onto a clean, flat, wood or concrete subfloor or existing flooring should be troweled and lay down the sheets, planks, or tiles. No vapour barrier is required. Some glue-down flooring is simply peel-and-stick, the easiest to install. Floorings should not be installed over a concrete sealer or painted concrete. If present, it should be removed by gridding or sanding. Floorings should not be installed over slick, heavily troweled or burnished concrete. For glued down floorings, when installing products wider than 8 cm, a bead of recommended wood glue to all the end grooves prior to installing into the adhesive should be applied.
Hybrid floorings	Hybrid flooring means the next generation of floor coverings that combine several aspects of wood, laminate and resilient floorings. The hybrid floorings can be made of a wide range of materials depending on the properties and characteristics that want to be achieved. Among these materials are ceramic, vinyl layers or resilient plastics.
IFL	Intact Forest Landscape Continuous propagation of natural ecosystems within the zone with current forest spread, showing no sign of significant human activity. The area is large enough to maintain all natural biodiversity, including viable populations of widespread species.
Ingoing substances and impurities	<b>Ingoing substances:</b> All substances in the chemical product regardless of amount, including additives (e.g., preservatives and stabilisers) from the raw materials. Substances known to be released from ingoing substances (e.g., formaldehyde, arylamine, in situ-generated preservatives) are also regarded as ingoing substances.  <b>Impurities:</b> Residues from production, incl. raw material production, which remain in the chemical product at concentrations below 1000 ppm (0.1000% by weight).  Examples of impurities are residues of reagents incl. residues of monomers, catalysts, by-products, scavengers (i.e., chemicals that are used to eliminate/minimise undesirable substances), detergents for production equipment and carry-over from other or previous production lines.
IUCN	International Union for Conservation of Nature IUCN's Red List is the world's most comprehensive overview of the global conservation status of the planet's species, including trees.
Laminate	Laminate means a process in which paper is used in the product, e.g., melamine, HPL or compact laminate.
Laminate flooring	Laminate flooring means, in accordance with the definition provided in the EN 13329, a floor covering with a surface layer consisting of one or more

	thin sheets of a fibrous material (usually paper), impregnated with aminoplastic, thermosetting resins (usually melamine), pressed or bonded on a substrate, normally finished with a backer. Two main classes of laminates are produced depending on the process of manufacture, High pressure laminate (HPL) and direct pressed laminate (DPL).
Linoleum	A natural product made of linseed oil, wood, limestone, cork, and resins.
Nanomaterial	'Nanomaterial' means a natural, incidental or manufactured material consisting of solid particles that are present, either on their own or as identifiable constituent particles in aggregates or agglomerates, and where 50 % or more of these particles in the number-based size distribution fulfil at least one of the following conditions: (a) one or more external dimensions of the particle are in the size range 1 nm to 100 nm; (b) the particle has an elongated shape, such as a rod, fibre or tube, where two external dimensions are smaller than 1 nm and the other dimension is larger than 100 nm; (c) the particle has a plate-like shape, where one external dimension is smaller than 1 nm and the other dimensions are larger than 100 nm.
PEFC	Programme for the Endorsement of Forest Certification Certification scheme for forestry and traceability in the supply chain
Recycled materials	Recycled materials are defined according to ISO 14021 in the following two categories: "Pre-consumer/commercial" is defined as material diverted from the waste stream during a manufacturing process. Excluded is reutilization of materials such as rework, regrind or scrap generated in a process and capable of being reclaimed within the same process that generated it. Nordic Ecolabelling defines rework, regrind or scrap, that cannot be recycled directly in the same process, but requires a reprocessing (e.g., sorting, remelting and granulation) before it can be recycled, to be pre-consumer/commercial material. This is regardless of whether it is produced in-house or externally. "Post-consumer/commercial" is defined as material generated by households or by commercial, industrial and institutional facilities in their role as end-users of the product, which can no longer be used for its intended purpose. This includes returns of material from the distribution chain. Materials that are approved as input in FSC Recycled and which are covered by the term Reclaimed in FSC are regarded as recycled material.
Renewable raw materials	Resources that have a natural rate of availability and yield a continual flow of services which may be consumed in any time period without endangering future consumption possibilities as long as current use does not exceed net renewal during the period under consideration. Wood is a renewable raw material while calcium carbonate is not.
Resilient flooring	Refers to floor coverings that occupy a middle ground between soft floors (like carpeting) and hard floors (like stone or hardwood). According to industry group Resilient Floor Covering Institute (RFCI), only six types of floor coverings can be called resilient flooring: Vinyl and other thermoplastic, linoleum, cork, rubber, asphalt and polymeric poured seamless floors.
Surface treatment	All techniques that aim to provide a twofold basic functionality: a) to protect the underlying material (wood, cork, bamboo-based materials) against deterioration by the adjacent environment and b) to decorate or improve the aesthetic aspect of the surface. Protection should be given against physical and chemical attacks, including water, chemical agents, UV-light and dirt. The aesthetic aspects refer to characteristics like colour performance, gloss and desire surface structure. The basic principle relies on the fact that most of the wood species, cork and bamboo are hygroscopic and absorb stain and lacquer in different ways depending on their porosity and the cell structure.
VOC	Volatile organic compounds (VOC) are defined as any organic compound having an initial boiling point less than or equal to 250°C measured at a standard pressure of 101.3 kPa. This definition is the same as in the Paints Directive (2004/42/EC).
Vinyl flooring	Vinyl comprises the majority share of the resilient flooring market. This includes Vinyl Composition Tile (VCT), Solid Vinyl Tile (SVT) and Luxury Vinyl Tile (LVT).

Wood-based panels	Example of wood-based panels and manufactured board: Particleboard MDF (Medium Density Fibreboard) HDF (High Density Fibreboard) MFB (Melamine Faced Board) Plywood OSB (Oriented Stranded Board) LVL (Laminated Veneer Lumber)
Wooden flooring	Wooden flooring is defined in accordance with prEN 13756 (revised in 2014) as the assembly of wood elements, pre-assembled boards or parquet panels which constitutes the wearing surface of the floor. This definition includes solid wood flooring, multi-layer wood flooring and wood veneer floor covering.

### 4.3 Overview of the requirements

The criteria are mainly divided into requirement areas where some of the requirements apply to all flooring types and underlays, while others only apply to certain product types. The table below provides an overview of the requirements that must be met for the different flooring types and underlays.

Requirement area	Requirement/Material	Requirement	Responsibility for documentation
<b>General requirements</b>			
Description of product, of the production process and overview of chemicals	General requirements	O1– O3	Product manufacturer
Share of renewable/recycled raw materials	General requirements	O4	Product manufacturer
Chlorinated plastics in floor coverings and flooring underlays	General requirements	O5	Product manufacturer
<b>Materials</b>			
Wood raw material	Nordic Swan Ecolabelled laminate and wood-based panel	O6	Wood-based panels manufacturer
	Tree species – restrictions	O7	Product manufacturer/Subcontractor
	Traceability and certification	O8	Product manufacturer
	Chemicals in reused wood and recycled material	O9	Product manufacturer/Subcontractor
Linoleum	Flax (linen), other bast fibres and linseed oil	O10	Product manufacturer
Other materials	Origin	O11	Product manufacturer/Supplier of material
	Recycled fibres - test for harmful substances	O12	Product manufacturer/Supplier of material
	Chemicals in recycled leather	O13	Product manufacturer/Supplier of material
Plastic, rubber and foam	Raw materials for bio-based polymers	O14	Product manufacturer/Supplier of material
	Emission to water from production of foams	O15	Supplier of material
	Blowing agents in foams	O16	Supplier of material
	Rubber, synthetic latex (SBR) and natural latex	O17	Supplier of material

	Recycled plastic, rubber and foam – Traceability	O18	Product manufacturer/Supplier of material
	Chemicals in recycled plastic, rubber and foam	O19	Product manufacturer/Supplier of recycled material
	Additives – Prohibited substances	O20	Product manufacturer/Supplier of material
Material based on recycled composite	Recycled composite	O21	Product manufacturer/Supplier of material
	Recycled composite - Additives – Prohibited substances	O22	Product manufacturer/Supplier of material
	Chemicals in recycled composite	O23	Product manufacturer/Supplier of material
<b>Production</b>			
Chemicals	Antibacterial substances	O24	Product manufacturer and chemical manufacturer/supplier of chemical product
	Classification of chemical products	O25	Product manufacturer/supplier of chemical product
	Classification of ingoing substances	O26	Product manufacturer/supplier of chemical product
	Preservatives	O27	Product manufacturer/supplier of chemical product
	Prohibited substances	O28	Product manufacturer/supplier of chemical product
	Nanomaterials	O29	Product manufacturer/supplier of chemical product
	Volatile organic compounds	O30	Product manufacturer/supplier of chemical product
	Free formaldehyde	O31	Product manufacturer/supplier of chemical product
Requirement specific to surface treatments	Application method and quantity applied – surface treatment	O32	Product manufacturer/surface treatment contractor.
	Environmentally harmful products and substances in surface treatment	O33	Product manufacturer
	Quantity of applied volatile organic compounds (VOC) in surface treatments	O34	Product manufacturer
Occupational hazard	Emissions to air from production of laminate	O35	Product manufacturer
	Polyurethane	O36	Product manufacturer/Supplier of material
Energy and Waste	Energy mapping	O37	Product manufacturer
	Energy consumption	O38	Product manufacturer/Supplier of material
	Handling of waste and production waste	O39	Product manufacturer
<b>Packaging</b>			
Packaging	Packaging	O40	Product manufacturer
<b>Use-phase requirements</b>			
Emission	Emissions from floor coverings and flooring underlays	O41	Product manufacturer
Quality and durability requirements	Product performance – third-party verification	O42	Product manufacturer
	Quality and durability of floor coverings	O43	Product manufacturer
	Quality and durability of flooring underlays	O44	Product manufacturer

	Wet room approval	O45	Product manufacturer
<b>Circular requirements</b>			
Circular requirements	Labelling and traceability	O46	Product manufacturer
	Warranty and Reparability	O47	Product manufacturer
	Recyclability	O48	Product manufacturer
	Product information	O49	Product manufacturer
<b>Innovation</b>			
Innovation	Innovation	O50	Product manufacturer/supplier of chemical product
<b>License maintenance</b>			
License maintenance	Customer complaints	O51	Product manufacturer
	Traceability	O52	Product manufacturer

## 4.4 General requirements

### O1 Description of the product and material composition

The floor covering or flooring underlays must be made of materials for which requirements are imposed in the criteria.

Materials for which requirements are not imposed must not account for more than 5%. Examples of materials that are not included in the criteria are concrete and ceramic materials.

The applicant must provide the following information about the product:

- Brand/trade name
- A description of the product/products (possibly including drawing/pictures) and the materials involved.
- Flooring type (e.g., wood, laminate, linoleum, plastic, hybrid) or underlays
- The market the product is intended for (private use, commercial use etc.)
- State the percentage composition of the material in the floor and the suppliers of the various materials (see requirement O4 for more information).

☒ A description in line with the requirement above. The template in Appendix 2 can be used by the flooring manufacturer to describe the composition of the materials. Product data sheets can be part of the documentation.

### Background

All the required information and especially, the material composition, is crucial for determining whether the floor covering, or underlays is eligible for the Nordic Swan Ecolabel, the requirements that must be met, and who (e.g., subcontractors/suppliers) must document the requirements. It is central for obtaining a good overview and a smooth licence processing procedure.

### O2 Description of the production chain and the manufacturing process

The manufacturing process and supply chain for the floor covering or underlays must be described. A flow chart can be used.

Make sure to include all production steps (examples can be seen in the table from the introduction to the energy requirements) and all materials/elements. Specify, if relevant, which finished layer/part(s) is purchased from suppliers and incorporated into the final product (e.g, backing foam, HDF, wood layer).

In case, a contract manufacturer is used to produce the final product, the following information must be submitted:

- The name of the contract manufacturer
  - The location of the production site (full address and country)
  - The contact information of a responsible.
- Submit a detailed description of the production chain and the manufacturing processes (a flow chart can be used). State which finished layer/part(s) is purchased, if relevant.
- Provide detailed information according to the points above in case a contract manufacturer is used to produce the final product.

## Background

To obtain a clear overview of the product, it is important to have a description of the manufacturing process, of the supply chain and of the different chemicals used during the process. This facilitates the assessment of which requirements in the criteria must be fulfilled and documented. Flow charts are usually good tools to illustrate the different manufacturing steps and the origins of the material used.

### O3 Overview of chemical products

All chemical products (e.g., adhesives/resins, additives and pigments, surface treatments and fillers) used in the manufacture of the floor coverings or underlays must be stated and documented with a safety data sheet.

The following information must be submitted for each chemical product:

- trade name
  - the function of the chemical
  - the process step in which the chemical product is used (the flow chart required in requirement O2 can be used).
  - the supplier/producer using the chemical product
- List of chemical products used in the manufacturing process.
- Safety data sheet in English (or Scandinavian) language for every chemical product, in line with Annex II of REACH 1907/2006.

## Background

To gain an overview of which chemicals are used in the various processes in the production, the criteria require the submission of a list of all the chemicals used.

### O4 Share of renewable and/or recycled raw materials

The requirement on the proportion of recycled and/or renewable raw materials must be calculated and met for the floor as a whole, including the laying/joining system.

Both flooring and underlays must meet one of the following three alternatives. The product must consist of:

- a) Minimum 90 % by weight of renewable raw materials
- OR
- b) Minimum 60 % by weight recycled materials\*, thereof at least half of it (30 % by weight) consist of post-consumer recycled materials.

OR

- c) Floorings and underlays that consist of both renewable and recycled material must comply with the following formula:

$$X + Y_1 + Y_2 \geq 70\% \text{ by weight}$$

X = Percentage by weight of renewable raw materials\*\*

Y<sub>1</sub> = Percentage by weight of pre-consumer recycled materials\*\*

Y<sub>2</sub> = Percentage by weight of post-consumer recycled materials\*\*

Non-organic fillers in the flooring may be exempted from the calculation of the weight percentage of the flooring where these are in principle available to an unlimited extent in nature\*\*\*.

Note that floor coverings and flooring underlays containing recycled composite material must also fulfil specific requirements from section 4.5.5.

*Example: A floor's total weight is 2500 g/m<sup>2</sup>. It consists of 900 g/m<sup>2</sup> fillers, 600 g/m<sup>2</sup> bio-based plastics (renewable), 250 g/m<sup>2</sup> post-consumer recycled plastics, 350 g/m<sup>2</sup> pre-consumer recycled plastics and 400 g/m<sup>2</sup> other materials (non-renewable nor recycled).*

*The proportion of renewable raw materials is: 600/1600 = 37,5%. The proportion of post-consumer recycled materials is: 250/1600 = 15,6%. The proportion of pre-consumer recycled materials is: 350/1600 = 21,9%. The combination of renewable and recycled materials is (600 + 250 + 350)/1600 = 75%.*

*\* Recycled material is defined in line with ISO 14021. See section 4.2 Definitions for more information.*

*\*\* Recycled renewable materials do not count as both renewable and recycled raw material.*

*\*\*\* This is the case for the fillers normally used in floors such as kaolin, calcium carbonate, calcium magnesium, carbonate, calcium sulphate, silicates and aluminium trihydrate (ATH). Nordic Ecolabelling reserves the right to assess whether a filler can be considered as being in such abundance that it may be considered as unlimited. Pigment does not count as fillers, but as additives.*

- Summary of the raw materials included in the floor stating the proportion of the raw materials as a percentage by weight. State which raw materials are renewable, and which are pre- or post-consumer recycled. Appendix 2 can be used.
- For alternative c), calculations showing that the requirement is fulfilled.

## Background

The RPS analysis shows that the cultivation or production of raw materials used in the manufacturing and construction of floor coverings or underlays has high relevance. Both processes are very energy and resource demanding and that is why they have a big influence on the overall environmental impact of the products.<sup>12,13</sup>

Production of virgin raw materials and especially those of fossil origins can contribute greatly to climate change. Most of the chemicals, polymers and plastics used in the manufacturing of floor coverings and underlays are still produced from oil and its extraction leads ultimately to an increase of greenhouse gases concentration in the atmosphere. Renewable raw materials are less impactful if considering their contribution to climate change. However, their

<sup>12</sup> <https://www.ivl.se/download/18.2eac00c7186755d386513d8d/1678965483510/B2463.pdf>

<sup>13</sup> <https://www.ivl.se/download/18.4c0101451756082fbad78/1603698658279/B2385.pdf>

contribution to diversity loss though land use has been proven and that is why it is important that, for instance, wood, cork and bamboo are cultivated in the less impactful manner (see material requirements for more information).<sup>14</sup>

Nordic Ecolabelled floor coverings and underlays must have a reduced overall environmental impact from a life cycle perspective. Hence, Nordic Ecolabelled strives to promote the use of responsibly sourced renewable and/or recycled raw materials in floor these products. Many manufacturers are already using recycled material to make new products. For instance, the installation of plastic and linoleum flooring generates approximately 10% scraps (pre-consumer recycled material). For many years, these scraps have been reintroduced into the manufacturing process of several producers to make new floor coverings. The access to post-consumer material of good quality/purity and the material's overall availability, especially for linoleum, has proven to be difficult. Lately, initiatives like Forbo's "Back to the floor recycling program" and Tarkett's ReStart® aim to increase the share of post-consumer recycled material in their floor coverings by recycling their own used floors. Even if these initiatives would guarantee an access to a lot of resource of known good quality/purity, they are still being slow down by complicated traceability and logistic challenges. Another way to reduce the products' contribution to climate change is to replace the fossil raw materials by vegetable crops. Hence, plastics whose building blocks are produced from renewable raw materials, or bio-based plastics, have been increasingly used in floor coverings.

Due to the material heterogeneity of the product group, the requirement can be fulfilled in three different ways. The first alternative a) requires that the floor consists of at least of 90% responsibly sourced renewable materials and is intended to be fulfilled only by solid wood floors, parquet, veneer, bamboo, cork floor coverings and floor coverings of similar construction. The second alternative b) requires the floor to consist of at least 60% recycled raw materials, thereof half of it must come from post-consumer recycled material. The last alternative c) allows also floors that consist of both recycled and renewable raw materials to fulfil this requirement. Renewable raw materials and recycled raw materials are weighted equally (see specific requirements on renewable materials in chapter 4.5 Materials for more details). The level of requirement and the limit value of 70% have been set so that only plastic, linoleum, hybrid and laminate floor coverings containing a certain share of recycled material in combination with responsibly sourced renewable raw materials can meet the criteria. It is worth noticing that the fillers are still not included in the calculations as it has proven difficult to source them as pre- or post-consumer recycled material. Pigments are not counted as a filler but as additive. Consequently, they must always be included in the calculations.

The requirement on the proportion of recycled and/or renewable raw materials must be calculated and met for the floor as a whole, including the laying/joining system. Examples of this include locking springs in milled grooves or permanently mounted aluminium rails. These components/materials amount to a very limited proportion of the materials for the entire floor, which is why the criteria document does not cover any specific material requirements for these. If

<sup>14</sup> [https://susproc.jrc.ec.europa.eu/product-bureau/sites/default/files/contenttype/product\\_group\\_documents/1581685016/Preliminary%20report%20sept%202014\\_revLCE\\_AB.pdf](https://susproc.jrc.ec.europa.eu/product-bureau/sites/default/files/contenttype/product_group_documents/1581685016/Preliminary%20report%20sept%202014_revLCE_AB.pdf)

an adhesive-free floor is instead sold with a separate laying system, this must also be counted in the percentage of the floor by weight.

#### O5 Chlorinated plastics in floor coverings and flooring underlays

Chlorinated plastics such as PVC (polyvinyl chloride) and PVDC (polyvinylidene chloride) must not be included in Nordic Ecolabel floor coverings nor flooring underlays.

- ☒ Declaration from the flooring manufacturer that the flooring is free from chlorinated plastics. Appendix 2 can be used.

### Background

The requirement covers both floor coverings and flooring underlays which may include PVC and/or PVDC as a material/component. Nordic Ecolabelling acknowledges that much has been done by industry to reduce the climate and health impact of PVC manufacturing and PVC products within the last 10 years. However, Nordic Ecolabelling reckons that the use of PVC in floor coverings and flooring underlays is still problematic for the following reasons:

- Although the recyclability of PVC and PVC products is undeniable, and PVC recycling systems are under development, it is still a challenge for the industry to collect, sort and process the material so that it does not contaminate new products with harmful legacy chemicals. Nordic Ecolabelling has looked into the possibilities of requiring take back systems for specific PVC product areas. Unfortunately, it may take time before all actors involved throughout the service life of a floor covering manage to run a fully functional take-back system.
- Although emissions of polyaromatic hydrocarbons (PAH), benzo-a -pyrene, dioxins and furans from incineration plants have been significantly reduced, and technologies for the management of air pollution control residues have been developed, not all the Nordic countries allow incineration of PVC. Denmark has a waste legislation that states that all PVC products must be sorted for material recycling. However, the difference in composition of products made of soft PVC (such as flooring) render their recycling difficult and must currently be sent to landfill, resulting in potential leaching of additives to the environment.<sup>15</sup> Furthermore, as a principle matter, Nordic Ecolabelling does not want to certify products that end up in landfills.
- Although the use of the most problematic phthalates is now restricted in the EU, other additives hazardous to the environment and health (e.g., plasticizers and stabilizers) can still be used in PVC as well as in other plastics.<sup>16</sup> The recent ECHA's work on a restriction proposal on the use of PVC and its additives is in line with Nordic Ecolabelling's specific concerns with PVC<sup>17,18</sup>.

<sup>15</sup> <https://op.europa.eu/en/publication-detail/-/publication/e9e7684a-906b-11ec-b4e4-01aa75ed71a1>

<sup>16</sup> <https://echa.europa.eu/sv/mapping-exercise-plastic-additives-initiative>

<sup>17</sup> [https://echa.europa.eu/documents/10162/17233/mandate\\_pvc\\_and\\_additives\\_rev\\_en.pdf/a860fd87-4231-5ed4-157b-f6cda1ee5832?t=1655721970555](https://echa.europa.eu/documents/10162/17233/mandate_pvc_and_additives_rev_en.pdf/a860fd87-4231-5ed4-157b-f6cda1ee5832?t=1655721970555)

<sup>18</sup> <https://echa.europa.eu/documents/10162/7d64f1d7-b29f-94ec-4477-9bcebf737a82>

- Although mercury cells are not used in Europe anymore, the replacing membrane technology requires the use of harmful substances (PFAS) to produce the chlorine gas needed in PVC and other chemicals/plastics production.<sup>19,20</sup> How much PFAS are released to the environment throughout the service life of the membrane and how the membrane is disposed afterwards as waste, are issues in need of more investigation.
- Although the purpose of Nordic Ecolabelling is to guide the consumer to choose the best products from an environmental perspective, communicating on potentially Nordic Ecolabelled PVC products could be challenging and be regarded as misleading. Additionally, there is a risk that the trustworthiness of the Nordic Ecolabel could be undermined if Nordic Ecolabelled vinyl flooring were to be found on the market, as many NGOs still advise to avoid the use of soft PVC products.

## 4.5 Materials

This chapter includes requirements for different materials such as wood (including bamboo and cork), linoleum, other raw materials, plastic, rubber, foam, and wood plastic composites used in floor coverings and underlays.

The requirements only apply to materials that accounts for more than 5 wt% of the floor covering or underlays. Water is exempted from all requirements.

Floor coverings and underlays consisting of several differing types of materials needs to comply with the specific material requirements e.g., a hybrid flooring must comply with requirements for wood raw materials and plastics raw materials. The same reasoning applies to underlays containing a combination of wood raw materials and other renewable raw materials.

Chemicals used in the production of finished layer/components included in floor coverings such as manufactured board or backing foams must fulfil requirements from section 4.6.1 Chemicals.

### 4.5.1 Wood raw materials

The requirements in this chapter concern raw materials such as wood, cork or bamboo that are included in underlays, wood flooring and manufactured boards used e.g., in wood (engineered or design floorings), laminate or hybrid floorings.

Wood raw material in paper must also fulfil requirements O7 and O8 if the floor coverings or flooring underlays contains more than 10 wt% paper.

#### O6 Nordic Swan Ecolabelled laminate and wood-based panel

If the laminate or wood-based panel in the floor covering is Nordic Swan Ecolabelled or included in a license in accordance with the Nordic Swan Ecolabel criteria for Panels and mouldings for interior use, generation 7 or later, the requirements in the chapter 4.5 Materials as well as requirements O35, is fulfilled.

---

<sup>19</sup> <https://eippcb.jrc.ec.europa.eu/reference/production-chlor-alkali-0>

<sup>20</sup> <https://www.eurochlor.org/publication/fluoropolymers/>

- Name, manufacturer and licence number of the laminate/wood-based panel.

## 07 Tree species – restrictions

Nordic Ecolabelling's list of tree species\* consists of virgin woods listed on:

- a) CITES (Appendices I, II and III)
- b) IUCN Red List, categorised as CR, EN and VU
- c) Rainforest Foundation Norway's tree list:
- d) Siberian larch (from forests outside the EU)

Exemption apply for:

- Eucalyptus and Acacia used in production of fibreboards and particle boards are exempted from the list (note\*\*).

Use of tree species listed on a) CITES (Appendices I, II and III) **is not permitted**.

Tree species listed on either b), c) or d) may be used if they meet all the following requirements:

- the tree species does not originate from an area/region where it is on the IUCN Red List, categorised as CR, EN or VU
- the tree species does not originate from an Intact Forest Landscape (IFL), as defined in 2002 <http://www.intactforests.org/world.map.html>.
- the tree species shall originate from FSC or PEFC certified forests/plantations and shall be covered by a valid FSC/PEFC Chain of Custody (CoC) certificate documented/controlled as FSC or PEFC 100% through the FSC transfer method or PEFC physical separation method.
- In addition, tree species grown in plantations shall originate from FSC or PEFC certified plantations established before 1994.

\* The list of tree species can be found on the website: <https://www.nordic-ecolabel.org/declare-items/pulp-and-paper/forestry-requirements/forestry-requirements-2020/>

\*\* Regarding wood chips, fibre raw materials from eucalyptus/acacia must be a minimum of 70% certified (see requirement O8).

- Enter the names of the tree species included in the product, Appendix 3a can be used.

- Declaration from the applicant/manufacturer/supplier that tree species listed on a)–d) are not used in the product, Appendix 3c can be used.

If species from the lists b), c) or d) are used:

- Valid FSC/PEFC Chain of Custody certificate from supplier/applicant/manufacturer covering the specific tree species and documenting that the wood is controlled as FSC or PEFC 100% through the FSC transfer method or PEFC physical separation method.

- The applicant/manufacturer/supplier shall document full traceability back to the certified forest unit and document the following:

- the wood does not originate from an area/region where it is on the IUCN Red List, categorised as CR, EN or VU.
- the tree species does not originate from an Intact Forest Landscape (IFL), as defined in 2002: <http://www.intactforests.org/world.webmap.html>

- For plantations, the applicant/manufacturer/supplier must document that the tree species does not originate from FSC or PEFC certified plantations established after 1994.

## Background

The requirement concerning tree species that are banned or restricted is new and part of Nordic Ecolabelling's general forestry requirements. The requirement only applies to virgin wood and not wood defined as recycled material in accordance with ISO 14021.

A number of tree species are not allowed to be used or are allowed only under certain conditions. The tree species are shown on a list, and the species on the list are based on tree species that are relevant to the Nordic Ecolabelling criteria, i.e. wood that may be relevant to use in Nordic Swan Ecolabelled products. Listed tree species are indicated by the scientific name and most common trade names. The scientific name/trade name is not always sufficient, as there may be more than one scientific name/trade name for the listed tree species, not all of which feature on the list.

Criteria for tree species on the list:

- a) Species listed in CITES Appendices I, II and III.
- b) IUCN Red List, categorised as Critically Endangered (CR), Endangered (EN) and Vulnerable (VU).
- c) Rainforest Foundation's list of tropical tree species
- d) Siberian larch (derived from forests outside the EU)

Use of species on the CITES list in Nordic Swan Ecolabelled flooring and underlayment products is prohibited. CITES is an international convention for the control of trade (across borders) in wild fauna and flora. Depending on how endangered they are, the tree species in CITES are listed in Appendix I, II or III. Species listed in Appendix I are critically endangered and trading in these species is completely forbidden. Special permits for import and export are required for species in Appendices II and III. Trees with valid CITES permits are considered to be legally harvested under the EUTR (EU Timber Regulation). The Nordic Swan Ecolabel's ban on the use of tree species listed in CITES (Appendix I, II or III) goes beyond EU legislation. CITES regulates trade in endangered species, and there are also challenges concerning corruption in trade with wild animals and plants. Nordic Ecolabelling therefore does not wish to approve species on any of the appendices.

IUCN's Red List is the world's most comprehensive overview of the global conservation status of the planet's species, including trees. IUCN has established clear criteria to assess the risk of extinction according to the origin of tree species. These criteria cover all countries and all species in the world. Nordic Ecolabelling is aware that the IUCN Red List system focuses only on the extinction risk of species, and is therefore not designed for an overall assessment of whether a tree can be of sustainable origin. However, the list is updated continuously and is thus an important tool to estimate the conservation status of

a specific tree species globally. The Nordic Swan Ecolabel seeks to prohibit tree species listed as endangered (categories CR, EN and VU).

The Rainforest Foundation is an NGO in Norway that works to protect the world's remaining rainforests. At the moment, the Rainforest Foundation does not see any credible certification schemes operating in the tropics, and therefore recommends not buying tropical woods. The Rainforest Foundation has developed a list of tropical tree species based on tree species that are found on the Norwegian market. This list serves as a guide in complying with Norwegian guidelines for not using tropical wood in public-sector construction projects. Nordic Ecolabelling considers this to be a pragmatic approach for handling tropical wood in the Nordic market.

Siberian larch (with origins in forests outside the EU) is also on the tree list. Siberian larch is a sought-after type of wood in the construction industry due to its high quality. Species of this tree are widespread in the Eurasian North Boreal climate zone, with the species *Larix sibirica*, *Larix gmelinii*, *Larix cajanderi* and *Larix sukaczewii* particularly widespread in the large areas of Intact Forest Landscapes (IFL) in Russia. Siberian larch should be seen as an indicator species for boreal IFL areas that need to be kept intact.

#### *Exemptions:*

Exemption for the use of eucalyptus and acacia in production of fibreboards and particleboards: Eucalyptus and Acacia are grown in plantations for the specific use in the wood fibre and pulp/paper industry. Fibre raw material from acacia/eucalyptus must, however, be a minimum of 70% FSC/PEFC certified. The remaining proportion of fibre raw material must be covered by the FSC/PEFC control schemes. See requirement O8 for more information.

Nordic Ecolabelling is aware that wood on lists b), c) or d) may come from legal and sustainable forestry. Therefore, it is possible to use tree species listed under b), c) or d) if the applicant/manufacturer/supplier can demonstrate compliance with a number of strict certification and traceability requirements.

Many of the trees on the list grow in countries that still have large Intact Forest Landscapes (IFL). It is important to protect these for the sake of biodiversity and the climate. Several of these countries are at high risk of corruption, and national legislation relating to the environment, human rights and land ownership is often weak and/or not enforced by the authorities. There are different views on whether certification is good enough to meet the challenges of forest management in countries with a high risk of corruption and illegal logging. For example, relevant challenges related to this were published by Danwatch in a number of articles in 2018<sup>21, 22</sup>, and by redd-monitor.org in 2019<sup>23</sup>. Greenpeace International has terminated its membership of FSC for the reason that the certification body no longer fulfils its goals of protecting forests and human

---

<sup>21</sup> <https://danwatch.dk/undersogelse/dokumentfalsk-og-millionboeder-danske-byggemarkeder-saelger-trae-forbundet-til-ulovlig-hugst-i-amazonas/>

<sup>22</sup> <https://danwatch.dk/undersogelse/baeredygtighedsmaerke-er-ingen-garanti-for-baeredygtigt-trae/>

<sup>23</sup> <https://redd-monitor.org/2019/08/29/evicted-for-carbon-credits-new-oakland-institute-report-confirms-forced-evictions-for-green-resources-plantations-in-uganda/>

rights<sup>24</sup>. Other environmental organisations like WWF support certification as an important tool for sustainable forestry in these countries. Due to the uncertainty that FSC and PEFC certification systems are good enough to protect important areas of biodiversity and ethical aspects such as human rights and land ownership in areas with a high risk of corruption, Nordic Ecolabelling takes a precautionary approach and seeks further documentation about the tree species and its origins.

To document full traceability of the tree species, the applicant/manufacturer/supplier must present a valid FSC/PEFC Chain of Custody certificate covering the specific tree species and demonstrate that the wood is controlled as FSC or PEFC 100%, through the FSC transfer method or PEFC physical separation method. This means that the FSC percentage or credit control system and the PEFC percentage system are not approved. Full traceability of the wood back to the forest/certified forest unit makes it possible to document that the tree species does not come from an area/region where it is on the IUCN Red List, categorised as CR, EN or VU. Full traceability also makes it possible to document that the tree species does not come from an Intact Forest Landscape (IFL), as defined by Intactforest.org in 2002<sup>25</sup>. Intactforest has monitored IFL areas since 2000 and has developed an updated online map tool that shows the scope of IFLs back to 2002. The monitoring results show that the world's IFLs are disappearing at an alarming rate, which is why Nordic Ecolabelling refers to 2002.

Plantations: Nordic Ecolabelling believes that responsibly managed forest plantations can play a role in preserving natural IFLs by reducing the pressure to cut down the world's remaining natural forests. In order to ensure that the plantation has not replaced original ecosystems (forests/grasslands) over the last 25 years, tree species must come from FSC or PEFC certified plantations that were established before 1994. 1994 follows FSC's international forest management standard (version 5.2), while PEFC works with 2010.

## 08 Traceability and certification

The requirement applies to wood raw material, cork and bamboo used in the product.

### **Species name**

The applicant/manufacturer must state the name (species name) of the wood raw material/bamboo/cork used in the product.

### **Chain of Custody certification**

All wood raw material and bamboo used in Nordic Swan Ecolabelled products must be covered by a valid Chain of Custody certificate in accordance with FSC/PEFC schemes.

The applicant or product manufacturer must have Chain of Custody certification under the FSC/PEFC schemes.

### **Certified wood raw material, bamboo and cork**

A minimum of 70% by weight/volume of the wood raw material, bamboo and cork used in the Nordic Swan Ecolabelled product must come from forests that

---

<sup>24</sup> <https://www.greenpeace.org/international/press-release/15589/greenpeace-international-to-not-renew-fsc-membership/>

<sup>25</sup> <http://www.intactforests.org/world.webmap.html>

are managed in accordance with sustainable forestry management principles established by FSC and PEFC and/or be recycled raw material\*.

### For oak parquet floor covering:

The minimum total share of wood raw materials (weight/volume) used in oak parquet floor covering must come from forests that are managed in accordance with sustainable forestry management principles established by FSC and PEFC and/or be recycled raw material\* according to below table:

Deadline	01/01/2025	01/01/2026	01/01/2027
Required share of certified wood raw material (%)	Minimum 60	Minimum 65	Minimum 70

The remaining proportion of wood raw material must be covered by FSC/PEFC's control schemes (FSC controlled wood/PEFC controlled sources) or be recycled material.

The applicant/manufacture must create a designated product group for Nordic Swan Ecolabelled products in their accounting system to control and meet the required certified content in Nordic Swan Ecolabelled products.

\*See *Definitions*.

For more information, see appendix 4.

- The names (species names) of the wood raw material, bamboo and cork that are used, appendix 3a can be used.
- The applicant/manufacture must provide valid FSC/PEFC CoC certification that includes all wood raw material, bamboo and cork used in the Nordic Swan Ecolabelled product.
- The applicant/manufacture shall provide audited accounting documents showing that at least 70% (60 to 70% for oak parquet) of the material in the Nordic Swan Ecolabelled product or production line is from forests or areas that are managed in accordance with sustainable forestry management principles that meet the requirements of the FSC or PEFC scheme. If the product or production line includes uncertified material, evidence must be provided that the content of uncertified material does not exceed 30% (30 to 40% for oak parquet) and is covered by a verification system that ensures that it is legally harvested and meets any other requirements laid down by FSC or PEFC with regard to uncertified material.
- An applicant/manufacture who only uses recycled material in the Nordic Swan Ecolabelled product, which is not FSC/PEFC certified, must provide documentary evidence that the material is recycled, e.g., an invoice.
- The proportion of wood raw material derived from certified forests must be stated and the basis for calculations must be shown. Appendix 3b can be used.

## Background

Nordic Ecolabelling's requirements concerning raw material based on wood, bamboo or cork focus on sustainable forestry and traceability of raw materials.

The many benefits that sustainably managed forests deliver to society include wood for materials and energy, protection against global warming, homes and livelihoods for local communities and indigenous peoples, support of biodiversity and protection of water and soil from pollution and erosion. By setting a

requirement that wood raw material must originate from certified, sustainably-managed forests, Nordic Ecolabelling is supporting the move towards more sustainable forestry practices.

Nordic Ecolabelling requires a declaration of the species of wood contained in the Nordic Swan Ecolabelled product. This makes it possible to check the validity of Chain of Custody certificates in the supply chain. The requirement for CoC certification improves the traceability of materials in the supply chain within the guidelines and control systems of the FSC and PEFC. The company's CoC certification proves how certified wood is kept separate from other wood during production, administration and storage and is inspected annually by independent certification bodies.

The manufacturer of the product must be CoC certified, and there is a requirement that certified raw material must be assigned/allocated to the Nordic Swan Ecolabelled product in the accounts for certified/non-certified material. This ensures that FSC/PEFC credits are used for the Nordic Swan Ecolabelled production and that the credits are "used up" and not sold twice. This will stimulate increased demand for certified wood raw material because more certified wood raw material must be purchased if the manufacturer wants to label other products, and not just the Nordic Swan Ecolabelled products, with the FSC/PEFC logo. This also means that it is possible to label the finished product with the FSC/PEFC logo and that a Nordic Swan Ecolabelled product can carry both the Nordic Swan Ecolabel logo and the FSC/PEFC logo. It should be noted that Nordic Ecolabelling approves both the percentage system and the credit system for accounting and sale of certified material.

Because PEFC/FSC certified oak is difficult to find in the Nordic countries and that war between Ukraine and Russia has put a pressure on its importation, Nordic Ecolabelling has decided to introduce a specific requirement on parquet containing oak. A stepwise increase share of certified wood raw material from 60 to 70% over 3 years is required specifically for oak parquet. All other wood-based floor coverings must fulfil the limit value of 70% PEFC/FSC certified wood raw material from the beginning of criteria validity.

## 09 Chemicals in reused wood and recycled material

Recycled material in floor coverings, underlays and wood-based panels (e.g., particle boards and fibreboards) must meet the requirements of the European Panel Federation's (EPF) Standard for delivery conditions of recycled wood<sup>26</sup>.

This means that the materials must not contain

- Treated wood\*
- Wood that exceeds the threshold limit values in the table below:

Substance/compound	Limit value (mg/kg recycled wood)
Arsenic (As)	25
Cadmium (Cd)	50
Chromium (Cr)	25
Copper (Cu)	40
Lead (Pb)	90
Mercury (Hg)	25

<sup>26</sup> <https://europanel.org/issues/standards/>

Fluorine (F)	100
Chlorine (Cl)	1000
Pentachlorophenol (PCP)	5
Creosote (Benzo(a)pyrene)	0.5

The requirement does not apply to sawdust, wood chips and similar materials that come straight from the wood-processing industry where the wood is virgin/untreated.

*\* The standard defines treated wood as wood that contains halogenated organic compounds, creosote or heavy metals as a result of treatment with wood preservatives.*

- Certification or equivalent documentation of compliance with the EFP's Standard for delivery conditions of recycled wood

## Background

The requirement is set to have better control over the type of recycled material used and to ensure that materials containing undesirable substances are not used. The requirement is the same as that set out in Nordic Ecolabelling's Criteria for furniture and fitments (generation 5) and the EU Ecolabel Criteria for furniture. Compliance with this standard is relatively good in the EU but it is important to ensure that production outside the EU also complies with the requirements of the standard. Requirements are imposed on the content of a number of heavy metals and creosote. If it can be documented that the requirements of the German Waste Wood Ordinance regulation, 2002 or later are met, this will also be approved as documentation.

The definition of 'treated wood' has been updated after consultation to also include wood treated with creosote due to a consultation comment from the Danish Environmental Protection Agency, with reference to the restriction proposal<sup>27</sup>.

### 4.5.2 Linoleum

The requirements in this section cover raw materials used in the manufacture of linoleum flooring. Both jute used in the backing of the flooring and linseed oil used in the manufacture of the linoleum cement must fulfil the requirements. Because linoleum flooring manufacturers may buy their raw materials from a multitude of suppliers, it may be accepted that the license holder documents the requirement for 50% of its jute and linseed oil total purchases.

The chemicals used in the manufacture of the linoleum cement must fulfil the requirements from the section 4.6.1 Chemicals.

#### O10 Flax (linen), other bast fibres and linseed oil

Flax (linen), other bast fibres (e.g., hemp, jute, and ramie) and linseed oil may only be cultivated/harvested from cultures using pesticides permitted according to Regulation (EC) No 1107/2009.

Production of flax (linen) and other bast fibres (e.g., hemp, jute, and ramie) using water retting is only allowed if the wastewater from the retting ponds is

<sup>27</sup> <https://echa.europa.eu/da/registry-of-restriction-intentions/-/dislist/details/0b0236e186d2119a>

treated to reduce the chemical oxygen demand (COD) or the total organic carbon (TOC) by at least:

- 75% for hemp fibres
- 95% for flax (linen) and other bast fibres

*Test method: Test in accordance with ISO 6060.*

*Measurement of BOD (Bio-chemical oxygen demand), PCOD (particulate chemical oxygen demand) or TOC (total oxygen demand) may also be used if a correlation to COD is evident.*

*The requirements for analysis laboratory and test methods are stated in Appendix 1.*

- Statement from the fibre/linseed oil supplier that only approved pesticides are used. Alternatively, a valid certificate from European Flax Standard or equivalent can be used.
- Test report from the producer of the flax (linen)/bast fibre, showing that the water retting requirement is fulfilled.

## Background

The use of natural and renewable raw materials has the advantage that it does not draw directly on fossil resources. It remains relevant, however, to consider whether these renewable raw materials are sustainably cultivated with minimum damage to the environment. It is, for example, important to ensure that there has been no use of harmful pesticides that could lead to a loss of biodiversity. The requirement can be documented by sending a European Flax Standard certificate or equivalent. According to this standard, the flax is grown following European legislation EU 1107/2009. It is not uncommon for flax from Europe to be sold to countries in Asia for use in textiles and several Asian productions have a certificate for the European Flax Standard.

Water retting is prohibited unless the wastewater is cleaned to reduce the content of organic material and so comply with the requirement levels. Either biological or chemical retting is necessary to separate the fibres from the inner stem and the outer shell. This is done by exposing the stem or other bast fibre to moisture and heat. Water retting is the most effective method, but there are other methods such as placing the fibres in a tank and adding enzymes. Emissions of retting wastewater with a high content of organic material to the aquatic environment can result in a lack of oxygen during degradation, which can damage the aquatic animal and plant life. Requirements for water retting are not covered by the European Flax Standard.

Nordic Ecolabelling is aware that linoleum flooring manufacturers may buy their raw materials from a multitude of suppliers making the documentation of this requirement a time-consuming task. That is why, it can be accepted that the license holder documents the requirement for 50% of its raw material purchases. This option may give more flexibility and may speed up the documentation process by focusing on the bigger suppliers.

### 4.5.3 Other materials

The requirements in this section concern other materials than the ones usually used in resilient floor coverings or flooring underlays. Requirement O11 must be fulfilled regardless the quantity of other materials contained in the product. In

addition, requirements O12 and O13 must be fulfilled only if the quantity of, in this case, textile and/or leather exceeds 10% in the product.

## O11 Origin

The raw material must be either:

- a) waste\* or residual products\* from other production systems, e.g., straw from grain production or,
- b) 100% pre- or post-consumer recycled (e.g., recycled textile, recycled fibres or recycled leather). See section 4.2 Definitions for more information.

*The species name (Latin and English/Nordic language) and geographic origin (country) must be stated in case the raw material is or renewable origin.*

*\*\*Waste and residues as defined in EU Directive 2018/2001/EC. Examples of residual products include straw, chaff and the non-edible part of maize.*

### Recycled synthetic fibres

The recycled plastic used as raw materials in recycled synthetic fibres must not have undergone any recycling process approved and published on EFSA's\*\* and/or FDA's\*\*\* official list.

*\*\* In line with article 9 from Commission Regulation (EC) No 2022/1616 of 22 September 2022 on recycled plastic materials and articles intended to come into contact with foods (<https://eur-lex.europa.eu/legal-content/EN/TXT/PDF/?uri=CELEX:32022R1616&qid=169683184440>)*

*\*\*\* In line with the Code of Federal Regulations Title 21: Food and Drugs, PART 177 – INDIRECT FOOD ADDITIVES: POLYMERS ([https://www.cfsanappsexternal.fda.gov/scripts/fdcc/index.cfm?set=RecycledPlastics&sort=Recycle\\_Number&order=DESC&startrow=1&type=basic&search=](https://www.cfsanappsexternal.fda.gov/scripts/fdcc/index.cfm?set=RecycledPlastics&sort=Recycle_Number&order=DESC&startrow=1&type=basic&search=)).*

### Recycled leather

Only skins and hides from the following animals can be used in the recycled leather: fish\*, sheep, goats, cattle, horses, pigs, elk, deer and reindeer.

*\*skin from fish on the IUCN Redlist is not allowed.*

- Alternative a): Name and geographic origin of the raw material if relevant. Documentation from the raw material producer which shows that the requirement's definition of waste or residual products is met. Documentation regarding traceability stating where the waste or residual product comes from.
- Alternative b): Declaration that the renewable raw material is also 100% post-consumer recycled. Documentation in the form of an invoice or delivery note from the manufacturer of the recycled material.
- Recycled synthetic fibres: Declaration from the producer of the recycled raw material that it has not undergone any recycling process approved by EFSA or FDA, see requirement.
- Recycled leather: The applicant must provide a declaration from the recycled leather manufacturer or recycled leather supplier that the hides/skins used have come from animals farmed for production of milk, wool and/or meat/fish.

## Background

Nordic Ecolabelling is positive about the use of renewable materials but wishes to receive information about their origins as well as, if relevant, the species or type used and their geographical origin. It is important that the renewable raw

materials have a sustainable origin and are not suitable for other important uses, such as human food or animal feed. There is therefore a requirement that the raw materials must be waste/residues products or recycled materials from other production.

Nordic Ecolabelling wants to support the circular economy through the use of recycled materials instead of virgin materials. However, fibre to fibre recycling is still limited for textiles and recycled polymers from other synthetic materials are frequently used today as different plastic materials. The requirement thus accepts both fibre to fibre recycling and polymer fibre recycling. Recycled cotton fibre recovered from used clothing and textiles from consumers or industrial waste (post- or pre-consumer textile waste) is also becoming more available.

The requirement stipulates that feedstock used in the recycled raw material must be fully traceable. Without proper traceability, it is difficult to ascertain that the material is recycled. The manufacturer of the recycled raw material can document the traceability by declaring that 100% recycled feedstock has been used.

Prohibition on the use of re-granulate resulting from reprocessing processes that have obtained an approval pursuant to Commission Regulation (EC) No 2022/1616 on recycled plastics materials and articles intended for food contact or approval pursuant to the Code of Federal Regulations Title 21: Food and Drugs, PART 177 — INDIRECT FOOD ADDITIVES: POLYMERS. Plastic materials approved for food packaging require the highest traceability and purity of the plastic raw material and it will therefore be down cycling to use this plastic for anything other than food contact products.

The aim of the requirement is to ensure that only hides that are a by-product of the meat/dairy/wool industries are used. This mitigates the environmental impact of livestock, and it makes sense from an ethical point of view that the leather and hides produced are derived from a by-product of the meat/dairy/wool industries. Fish skin provided it is not on the IUCN Redlist, is now also included in this version of the criteria. Fish skin must comply with the same requirements as other types of skin and leather.

## O12 Recycled fibres - test for harmful substances

Recycled fibres must not contain the following substances above the limits stated in the table below:

Substance/substance group	Max. limit	Test method
<b>Extractable metals</b>		Atomic absorption spectrometry (AAS) or ICP. The metals are extracted by use of artificial acidic sweat solution according to ISO 105-04 (testing solution II).
Chromium total	2.0 mg/kg	
Lead	1.0 mg/kg	
Mercury	0.02 mg/kg	
Cadmium	0.1 mg/kg	
<b>Organic tin compounds</b>		
TBT and TPhT	0.5 mg/kg	
<b>Phthalates</b>		Extraction of the testing material with an organic solvent. The extract is analysed by gas chromatography (MS detection).

BBP, DBP, DEP, DMP, DEHP, DMEP, DIHP, DHNUP, DCHP, DHxP, DIBP, DIHxP, DIOP, DINP, DIDP, DPrP, DHP, DNOP, DNP and DPP	Total 0.05 weight%
<b>PAHs (Polycyclic aromatic hydrocarbons)</b>	Extraction of the testing material with an organic solvent. The extract is analysed after clean-up by gas chromatography with mass selective detection (MSD).
Naphthalene, Acenaphtene, Acenaphtylene, Phenanthrene, Anthracene, Fluorene, Fluoranthene and Pyrene	Each 1 mg/kg
<b>Flame retardants</b>	Extraction of the testing material with an organic solvent. The extract is analysed then by LC/MS/MS respectively GC/MS/MS.
Brominated and chlorinated flame retardants	Total 50 mg/kg
<b>Chlorophenols</b>	The samples are extracted with a basic aqueous solution following DIN 50009. The extracted free phenols and possibly hydrolysed phenolesters are acetylated, transferred to an organic phase and analysed with GC-MS.
Pentachlorophenol	0.5 mg/kg
Tetrachlorophenol	0.5 mg/kg
Trichlorophenol	2.0 mg/kg
Dichlorophenol	3.0 mg/kg
Monochlorophenol	3.0 mg/kg
<b>Per- and polyfluorinated compounds</b>	The method for the determination of PFCs/PFAS is based on an extraction with methanol followed by determination of the PFCs/PFAS by means of LCMS and GC-MS.
PFOS, PFOSA, PFOSF, N-Me-FOSA, N-Me-FOSE, N-Et-FOSE	Total <1.0 µg/m <sup>2</sup>
PFHpA, PFNA, PFDA, PFUdA, PFDaA, PFTrDA, PFTeDA	0.025 mg/kg for each
PFOA and salts	Total <0.025 mg/kg
PFOA related Substances as stated in OekoTex 100 Annex 4 and 5.	Total <0.25 mg/kg
Other stated per- and polyfluorinated compounds as set out in OekoTex 100 Annex 5.	0.025 or 0.25 mg/kg for each as stated in Oeko-Tex 100
<b>Organic fluorine content</b>	
Extractable organic fluorine (EOF)	10 mg/kg
<b>Dyes</b>	EN 14362-1 EN 14362-3 The identification and quantification of dyes extracted with an organic solvent is made by means of chromatographic methods.
Cleavable, classified as carcinogenic	20 mg/kg
Cleavable aniline	50 mg/kg
Classified as carcinogenic	50 mg/kg
Dyes classified as allergenic	50 mg/kg
Other dyes	50 mg/kg

This requirement applies to all recycled fibres – both synthetic and natural and must be documented annually with either a) or b):

- a) an Oeko-Tex standard 100 class I-III certificate.

- b) test report showing that the requirement is fulfilled.

The following are exempted from this requirement:

- Material from PET bottles originally approved for food contact. Please note that rPET that has undergone any FDA/EFSA approved recycling process may not be used (see requirement O11).
- Fibres from chemically recycled polymers, if it can otherwise be documented that the process ensures, that the requirement limits are met.

*The requirements for analysis laboratory and test methods are stated in Appendix 1.*

- ☒ Test reports or Oeko-Tex 100 class I-III certificate showing fulfilment of the requirement. A written procedure showing how an annual test is performed in line with the requirement, along with annual in-house checks of compliance with the requirement. Alternatively, a procedure for annual requisition of Oekotex 100 class III certificate. Test results/certificate are to be archived and kept available for inspection by Nordic Ecolabelling.
- ☒ When using chemically recycled polymers, documentation showing that the recycling process ensures that the requirement is fulfilled.
- ☒ When using the exemption for material from PET bottles, this must be documented by the fibre supplier.

## Background

It is important to consider the potential exposure of the user and the environment to undesirable chemicals from recycled material. The requirement covers the chemical substances and substance groups that are at greatest risk of being present in recycled fibre for textile production. Recycled fibre may contain residues of additives from previously used dyes, pesticides from cultivation, biocides used during transport, and so on<sup>28</sup>. This applies to both fibre recovered from used textiles and fibre recovered from products other than textiles.

In mechanical recycling processes, all the chemical substances remain in the fibre and may be transferred to the new textile fibre. In the chemical recycling process, some chemical substances remain in the material, and both unproblematic and problematic substances can cause technical interference with the process<sup>29</sup>. It is possible to conduct a spot test for the most relevant substances over a set interval, but since the recycled feedstock may come from multiple sources and can therefore vary a great deal, it is not possible to implement the testing required to identify all the potential “old additives”.

Recycled PET (rPET) that has undergone any recycling process approved by EFSA or FDA as food contact material may not be used as a raw material. Safe access to recycled plastics of best quality must continuously be ensured for

---

<sup>28</sup> IKEA and H&M analyze the content of recycled fabrics, article 29-10-2019 on Treehugger.com [https://www.treehugger.com/sustainable-fashion/ikea-and-hm-analyze-content-recycled-fabrics.html?utm\\_source=TreeHugger+Newsletters&utm\\_campaign=9cd1c025b2-EMAIL\\_CAMPAIGN\\_11\\_16\\_2018\\_COPY\\_01&utm\\_medium=email&utm\\_term=0\\_32de41485d-9cd1c025b2-243762625](https://www.treehugger.com/sustainable-fashion/ikea-and-hm-analyze-content-recycled-fabrics.html?utm_source=TreeHugger+Newsletters&utm_campaign=9cd1c025b2-EMAIL_CAMPAIGN_11_16_2018_COPY_01&utm_medium=email&utm_term=0_32de41485d-9cd1c025b2-243762625)

<sup>29</sup> Nordic Council of Ministers (2016). Gaining benefits from discarded textiles: LCA of different treatment pathways

manufacturers of food contact packaging. PET that has undergone other recycling processes than one of those approved by EFSA or FDA may however be used. Recycled fibre from PET bottles may also contain small amounts of undesirable substances such as antimony and heavy metals, which are derived from labels, adhesives, printing inks and waste from the transport and sorting of the plastic. However, measurements have established that the levels fall well below the limits set for heavy metals in packaging materials in California's Toxics in Packaging Prevention Act of 2006<sup>30</sup>.

### O13 Chemicals in recycled leather

The requirement applies to chemicals in the recycled\* leather.

#### **Chromium**

The extractable Chromium content of the recycled leather must be less than 200 mg / kg (mass of Chromium (total) / dry weight of leather) according to EN ISO 17072-1.

Recycled leather must not contain Chromium VI in compliance with EN ISO 17075 (detection limit 3 ppm) or equivalent test method.

#### **Cadmium and Lead**

Cadmium and Lead shall not be found in recycled leather.

The content of Cadmium and Lead shall be tested according to the methods AAS, ICP-OES or ICP-MS (detection limit 10 ppm).

*\*See section 4.2 Definitions for more information.*

*The requirements for analysis laboratory and test methods are stated in Appendix 1.*

- A test report showing that the requirement on total Chromium and Chromium (VI) is fulfilled.
- A test report showing that the requirement on Cadmium and Lead is fulfilled.

### **Background**

Release of Cr (VI) compounds is a problem as hexavalent chromium compounds are contact allergens. Cr (VI) is one of the most well-known allergens. Hexavalent chromium (Cr (VI)) is not used in the tanning industry and has no effect in the tanning process. However, chromium (III) salts can - under certain conditions - be converted to Cr (VI) compounds.<sup>31</sup> Regardless of which tanning process is used, it is relevant to ensure that the content of chromium and especially chromium (VI) in the leather is documented and low.

The requirement is also set to ensure that there is no cadmium and lead in the leather. Lead occurs most often due to contaminants in the chromate during chromium tanning.

### **4.5.4 Plastic, rubber and foam**

The requirement in this section applies to all plastic (e.g., polyethylene, polypropylene and polyurethane and their derivatives), rubber and foam

---

<sup>30</sup> M. Whitt, Survey of heavy metal contamination in recycled polyethylene terephthalate used for food packaging, Journal of Plastic Film & Sheeting 2012

<sup>31</sup> Investigation and health related assessment (allergy only) of chromium in leather shoes

contained in floor coverings and underlays. Products including polyurethane must also fulfil the specific requirement O35 Polyurethane in section 4.6.3.

#### O14 Raw materials for bio-based polymers

Raw materials used in the production of bio-based polymers must meet the following requirements.

##### **Palm oil and soy**

Palm oil, soybean oil and soybean flour must not be used as raw material.

##### **Sugar cane**

Raw materials from sugar cane must either comply with a) or b):

- a) Waste or residual products\* defined in accordance with (EU) Renewable Energy Directive 2018/2001. There must be traceability back to the production / process where the residual production occurred.
- b) Certified according to Bonsucro standard (EU REDII approved), version 5.1 or later version. In addition sugar cane must not be genetically modified (see section 4.2 Definitions).

The producer of the bio-based polymer must have a chain of custody (CoC) certification according to the standard by which the raw material is certified. Traceability must at least be ensured by mass balance. Book and claim systems are not accepted.

The producer of the bio-based polymer must document its purchase of certified raw materials for polymer production, for example in the form of specifications on an invoice or delivery note.

##### **Other raw materials**

The name (in Latin and in English) and supplier of the raw materials used must be stated.

The raw materials must be waste or residual products\* defined in accordance with (EU) Renewable Energy Directive 2018/2001. There must be traceability back to the production/process where the residual production occurred.

Traceability must at least be ensured by mass balance. Book and claim systems are not accepted.

The producer of the bio-based polymer must document its purchase of certified raw materials for polymer production, for example in the form of specifications on an invoice or delivery note.

*\* Residual products as defined in EU Directive 2018/2001/EC. Residual products come from agriculture, aquaculture, fishing and forestry, or they can be processed residues. A processed residual product means a substance that is not the end product(s) that the production process directly seeks to produce; residues are not the primary target of the production process, and the process has not been deliberately modified to produce them. Examples of residual products are, for example, straw, bait, the non-edible part of maize, livestock manure and bagasse. Examples of processing residues are, for example, raw glycerol or brown lye from paper production. PFAD (Palm Fatty Acid Distillate) from palm oil is not considered a residual/waste product and may therefore not be used.*

- Declaration by the producer of the polymer, that palm oil (incl. PFAD (Palm Fatty Acid Distillate)) soybean oil and soy flour are not used as raw materials for the bio-based polymer.
- For waste and residual products: Documentation from the polymer producer which shows that the requirement's definition of waste or residual products is met. Documentation showing the level of certification (e.g., mass balance). Documentation regarding traceability stating where the waste or residual

product comes from. Name (in Latin and English) and geographical origin (country/state) of the primary raw materials used.

- ☒ Sugar cane b): Verify which certification system sugar cane is certified for. A copy of a valid CoC certificate or a certificate number. Documentation in the form of an invoice or delivery note from the manufacturer of bio-based polymer which shows that certified raw material has been purchased for the production of the polymer. Declaration stating that the sugar cane has not been genetically modified.

## Background

In terms of resources and climate impact, it is positive to use renewable raw materials instead of fossil fuels. However, it is important that the cultivation of bio-based raw materials is sustainable. Establishment of palm oil plantations is one of the main reasons for deforestation of rainforests, and thus threatens the livelihoods of indigenous people, plants and animals. Rainforests are very important for biodiversity and in regulating the climate. Soybeans are grown in areas that are often established at the expense of rainforests and forest waters in South America. Soy production is one of the biggest threats to the rainforest on the American continent, especially in the southern Amazon. Based on this, palm oil, soybean oil and soy flour are banned as raw materials for bio-based polymers.

Sugar cane is a relevant raw material for polymer production. Sugar cane is currently not as strongly associated with problems with deforestation of rainforest as mentioned above for palm and soybean oil, but there may also be challenges associated with this production. Sugar cane is permitted as a raw material, but it is required that it be certified according to a sustainability standard that meets several requirements for e.g., protection of biological diversity. For all certification systems, there is a requirement for traceability at the mass balance level. Book and claim system will not be approved.

In addition, there is a requirement that sugar cane must not be genetically modified. Genetic modification is a debated topic, and several countries have banned the cultivation of GMOs. Topics discussed are food safety, land use, lack of knowledge about effects under local agricultural / forest conditions and the risk of negative environmental and health impacts. Nordic Ecolabelling emphasizes the precautionary principle and regulations that have a holistic approach to GMOs. This means that sustainability, ethics, and societal benefits must be emphasized together with health and the environment. Concerns exist about the consequences when genetically modified plants, animals and microorganisms spread in nature. Nordic Ecolabelling believes that GMOs should be assessed on a case-by-case basis. Research results have not clearly shown that current GMO crops contribute to the development towards sustainable agriculture with less use of pesticides, and there is a lack of research on the long-term effects of genetically modified plants, both environmental consequences and socio-economic consequences. There are possible adverse effects of GMOs along the entire value chain from research and development of the plants, via cultivation, to storage, use and waste management. In several of these phases, there is a lack of scientific studies, and there is a lack of overall assessments.

For other primary raw materials, there is a requirement that the name of the raw material, supplier and origin of the raw material must be stated. The most ideal is to use waste and residual products from other productions, e.g., by-

products such as straw from cereal production and by-products from maize. By using secondary raw materials, parts that are not used as food are utilized. PFAD (Palm Fatty Acid Distillate) from palm oil is not considered a residual raw material and must therefore not be used. PFAD occurs in the production of palm oil for the food industry, and there is rarely traceability in the processes in which PFAD occurs. The requirement has been tightened after the consultation period, so that only waste or residual products defined in accordance with (EU) Renewable Energy Directive 2018/2001 from other raw materials than Bonsucro certified sugar cane may be used in bio-based polymer production.

#### O15 Emissions to water from production of foams

Emissions of oxygen demanding substances to water from the production of foam materials (e.g., EPS, XPS, EVA, PUR, PE, latex and rubber) must be reduced by 90% measured as COD or TOC. The reduction may be achieved through on-site or off-site treatment. In the case of off-site treatment, the average treatment level of the effluent treatment plant may be used.

*Chemical oxygen demand (COD) must be analysed under ISO 6060. The requirements for analysis laboratory and test methods are stated in Appendix 1.*

- ☒ Description of how the effluent from foam material production is treated and how COD emissions are measured and monitored.
- ☒ Test report showing that the limit value for chemical oxygen demand (COD) is fulfilled.

#### Background

Foam materials may be used as backing in floor coverings. Since there are environmental problems associated with the production of foam made of latex or polyurethane, it is relevant to set requirements concerning these. Nordic Ecolabelling requires emissions of oxygen demanding substances from the production to be low.

#### O16 Blowing agents in foams

CFC, HCFC, HFC, methylene chloride or other halogenated organic compounds must not be used as blowing agents in the manufacture of foam materials (e.g., EPS, XPS, EVA, PUR, PE and rubber).

- ☒ Information from the manufacturer of the foam stating which blowing agent has been used.

#### Background

Halogenated organic compounds may not be used as blowing agents or auxiliaries for these. Historically, CFC (ChloroFluoroCarbons), HCFC (HydroChloroFluoroCarbons) and HFC (HydroFluoroCarbons) have been used in the production of PU foam, and it is generally known that these substances are harmful to the environment, especially as greenhouse gases and as ozone depleting substances. The requirement prohibits the use of halogenated organic compounds that are used as blowing agents or auxiliaries for these. Many manufacturers of PU foam have replaced CFC and HCFC with carbon dioxide but ensuring that they are not used is still considered relevant. Blowing agents are only relevant for PU foam, as the production of latex foam does not require blowing agents. Expanded polystyrene uses water or pentane as a blowing agent.

## O17 Rubber, synthetic latex (SBR) and natural latex

### 1,3-butadiene

The content of 1,3-butadiene in synthetic latex must be less than 1 mg/kg latex and must be determined using test method EN 13130-4.

### PAHs

The sum of the PAHs concentration in rubber and latex must be below 10 mg/kg and each individual PAH concentration must be below 1.0 mg/kg.

The requirement concerns the following PAHs:

Substance name	CAS No.	Substance name	CAS No.
Benzo[A]Pyrene	50-32-8	Benzo[A]Pyrene	50-32-8
Benzo[E]Pyrene	192-97-2	Benzo[E]Pyrene	192-97-2
Benzo[A]Anthracene	56-55-3	Acenaphthylene	208-96-8
Dibenzo[A,H]Anthracene	53-70-3	Acenaphthene	83-32-9
Benzo[B]Fluoranthene	53-70-3	Anthracene	120-12-7
Benzo[J]Fluoranthene	205-82-3	Fluorene	86-73-7
Benzo[K]Fluoranthene	207-08-9	Naphthaline	91-20-3
Chrysene	218-01-9	Phenanthrene	85-01-8
Benzo[ghi]perylene	191-24-2	Fluoranthene	206-44-0
Indeno[1,2,3-cd]pyrene	193-39-5	Pyrene	129-00-0

The rubber material must be tested in accordance with ISO 18287 or ZEK 01.2-08 (GC/MS).

### Nitrosamines

The following requirements must be met for nitrosamines in rubber and latex material:

- The content of nitrosamines must not exceed 0.05 mg per kg rubber.
- The total content of nitrosamine-soluble substances must not exceed 1 mg per kg rubber.

*The requirements for analysis laboratory and test methods are stated in Appendix 1.*

- Results of an analysis/test for the content of 1,3-butadiene in synthetic latex.
- Results of an analysis/test for the content of PAHs in rubber.
- Results of an analysis/test for the content of nitrosamines in rubber and latex.

### Background

A number of synthetic latex materials are made of substances that are hazardous to the environment and human health, for example substances that are suspected to cause cancer. One substance that acts as a monomer in the production of latex is 1,3-butadiene (CAS No. 106-99-0) which has H340 and H350 classifications. There is therefore a requirement for content of butadiene to be tested to ensure that the monomer content of the final latex is low.

There are more than 100 PAHs compounds. Several of the PAHs are carcinogenic and classed as Carc. 1B. PAHs can be found in plastic and rubber parts in a wide range of consumer products. They are present as impurities in some of the raw materials used to produce such products, namely in plasticising oils and in carbon black. The substances are not intentionally added to the products in question, and they have no specific function as constituent ingredients of the

plastic or rubber parts. Extender oils are mineral oils that are produced from crude oil (PAHs that remain in the oil are called petrogens). Carbon black is the product of incomplete combustion or thermal decomposition processes of heavy oils, such as coal tar (PAHs that remain, however, are mainly pyrogenes PAHs). The requirement is harmonized with the levels in Oeko-tex 100 standard class II.

The requirement has been changed and harmonized with the level of requirements in the criteria for furnitures. Nitrosamines and nitrosamine-soluble substances are suspected to be carcinogenic. Nitrosamines are by-products formed in the production of rubber.

### O18 Recycled plastic, rubber and foam - Traceability

Recycled plastic, rubber and foam must not have undergone any recycling process approved and published on EFSA's\* and/or FDA's\*\* official list.

The traceability of the recycled raw material must be documented with either a) or b) below:

- a) Global Recycled Standard certificate or Recycled Claim Standard certificate showing that the raw material is recycled, or other equivalent certification approved by Nordic Ecolabelling.
- b) By giving the name of the recycled raw material producer, by documenting that the feedstock used is recycled material and by stating the share of recycled material included in the raw material, see 4.2 Definitions.

\* *In line with article 9 from Commission Regulation (EC) No 2022/1616 of 22 September 2022 on recycled plastic materials and articles intended to come into contact with foods (<https://eur-lex.europa.eu/legal-content/EN/TXT/PDF/?uri=CELEX:32022R1616&qid=1696831844440>).*

\*\* *In line with the Code of Federal Regulations Title 21: Food and Drugs, PART 177 – INDIRECT FOOD ADDITIVES: POLYMERS ([https://www.cfsanappsexternal.fda.gov/scripts/fdcc/index.cfm?set=RecycledPlastics&sort=Recycle\\_Number&order=DESC&startrow=1&type=basic&search=](https://www.cfsanappsexternal.fda.gov/scripts/fdcc/index.cfm?set=RecycledPlastics&sort=Recycle_Number&order=DESC&startrow=1&type=basic&search=))*

- Declaration from the producer of the recycled plastic that it has not undergone any recycling process approved by EFSA or FDA, see requirement.
- a) Certificate from an independent certifier of the supply chain (e.g., Global Recycled Standard or Recycled Claim Standard).
- b) Documentation in the form of an invoice or delivery note from the manufacturer of the floor covering or flooring underlays which shows that recycled material has been purchased to produce the product. Documentation in form of a statement from the recycled material producer, showing that the feedstock used is recycled material and showing the share of recycled raw material contained in the raw material.

### Background to the requirement

Nordic Ecolabelling wishes to support a circular economy by encouraging the use of recycled materials over virgin raw material – in this case crude oil. Substantial environmental potential is expected in the future with regard to reduce resource consumption and CO<sub>2</sub> emissions. However, availability and access to recycled polymers/plastics of good quality and purity is still challenging.

See requirement O11 for more information.

The requirement states that the feedstock used in the recycled raw material must be traceable. Without traceability, it is difficult to ensure that the material really is recycled. Traceability can be documented with a certificate from a third-party certifier of the supply chain, such as the Global Recycled Standard, for example. The Global Recycled Standard (GRS) is an international, voluntary standard that sets requirements for third-party certification of recycled content and chain of custody in the supply chain. This standard restricts the use of undesirable chemicals in the manufacture of new products, but the standard does not cover chemicals that may enter via the recycled materials, and thus gives no guarantee about what may be present in the finished GRS product<sup>32</sup> (see more on undesirable chemicals in recycled materials in requirement O19). It is up to Nordic Ecolabelling to assess if additional certification systems for recycled content can be accepted. Alternatively, traceability may be documented by the producer of the recycled raw material declaring that 100% recycled feedstock has been used.

### O19 Chemicals in recycled plastic, rubber and foam

The requirement applies to chemicals in the recycled\* plastic, rubber and foam raw material.

Recycled plastics, rubber and foams must not contain:

- halogenated flame retardants
- cadmium
- lead
- mercury
- chromium VI
- arsenic
- phthalates
- polycyclic aromatic hydrocarbons (Benzo[A]Pyrene, Benzo[E]Pyrene, Benzo[A]Anthracene, Dibenzo[A,H]Anthracene, Benzo[B]Fluoranthene, Benzo[J]Fluoranthene, Benzo[K]Fluoranthene, Chrysene)

Impurities up to 100 ppm are permitted.

*\*See section 4.2 Definitions for more information.*

*The requirements for analysis laboratory and test methods are stated in Appendix 1.*

- ☒ A test report (XRF, X-ray fluorescence, GC-MS or equivalent method) from the supplier of the recycled plastic, rubber and foam showing compliance with the requirement. Alternatively, the requirement can be documented with traceability to the source to substantiate that these substances are not included.

### Background

The requirement applies to chemicals contained in the recycled plastic raw material and not chemicals that are added through regranulation. There are separate requirements for this, see O28. The requirement must be documented with a test report using X-ray fluorescence (XRF), GC-MS or equivalent methods, or traceability to the source that substantiates that the specified substances are not included. The aim of the requirement is to capture the “worst substances”. There are different practices in the industry for testing substances in recycled plastics. Some manufacturers rely on questionnaires/declarations from their

<sup>32</sup> [Recycled Claim Standard \(RCS\) + Global Recycled Standard \(GRS\) - Textile Exchange](#)

subcontractors and follow them up with chemical analyses if it is considered likely that the plastic contains substances of concern. Some manufacturers of recycled plastic have XRF (X-ray fluorescence spectrometer) equipment for testing the plastic to see whether it can meet the given requirement (a level of 100 ppm can be achieved). Although this will entail extra documentation work, it shows that it is possible to set such a requirement. Using recycled plastic is good as it helps reduce resource use and stimulates a circular economy. At the same time, there is no wish to recycle chemicals that are harmful to health and the environment.

After the consultation 8 specific polycyclic aromatic hydrocarbons (PAH) have been added to the requirement. All 8 PAHs are listed in annex XVII in REACH due to risks to human health. PAHs have been found in plastic packaging made of recycled PCR plastic (PE and PP).<sup>33</sup>

## O20 Additives - Prohibited substances

Additives to plastic, rubber and foam (both virgin and recycled) must not be classified nor categorised according to the list below. The requirement applies to additives actively added to the polymer raw material in the compound or master batch in production of plastic, rubber and foam. The requirement also covers substances that are added during re-compounding of recycled plastic, foam or rubber raw materials.

The following substances must not be present:

- Substances on the Candidate List
  - The Candidate List can be found on the ECHA website: <http://echa.europa.eu/candidate-list-table>
  - Exemption applies to melamine (CAS No. 108-78-1)
  - D4 (CAS No. 556-67-2), D5 (CAS No. 541-02-6) or D6 (CAS No. 540-97-6) must only be included in the form of residues from raw material production and are allowed in concentrations up to 1000 ppm each in the silicone raw material.
- CMR substances - Carcinogenic, Germ cell mutagenicity, Reproductive toxicity category 1A or B or category 2 (including all combinations of stated exposure route and stated specific effect)
  - An exemption is made for titanium dioxide (CAS No. 13463-67-7) classified H351
  - An exemption is made for 1,1,1-Trimethylolpropane (TMP, CAS No. 77-99-6) classified H361
- Substances that have been judged in the EU to be PBT (Persistent, Bioaccumulative and Toxic) or vPvB (very Persistent and very Bioaccumulative)
  - PBT and vPvB in accordance with the criteria in Annex XIII of REACH
- Substances classified with hazard classes EUH440 (Persistent, Bioaccumulative and Toxic properties, PBT), EUH441 (Very Persistent, Very Bioaccumulative properties, vPvB), EUH450 (Persistent, Mobile and Toxic properties, PMT) and EUH451 (Very Persistent, Very Mobile properties, vPvM) according to lastly proposed revision of CLP regulation.

<sup>33</sup> <https://www2.mst.dk/Udgiv/publications/2023/04/978-87-7038-507-7.pdf>

- Endocrine disruptors: Substances on the EU member state initiative “Endocrine Disruptor Lists”, List I, List II and List III, see following links:  
*List I:* <https://edlists.org/the-ed-lists/list-i-substances-identified-as-endocrine-disruptors-by-the-eu>  
*List II:* <https://edlists.org/the-ed-lists/list-ii-substances-under-eu-investigation-endocrine-disruption>  
*List III:* <https://edlists.org/the-ed-lists/list-iii-substances-identified-as-endocrine-disruptors-by-participating-national-authorities>  
*Substances that are transferred to one of the corresponding sub-lists “Substances no longer on list” and that no longer feature on Lists I–III are not prohibited. However, this does not apply to the substances listed in Sub-List II that were evaluated on the basis of regulations or directives that do not have provisions for identifying endocrine disruptors (e.g., the Cosmetics Regulation). These substances may have endocrine disrupting properties. Nordic Ecolabelling will assess these substances on a case-by-case basis, based on the background information provided in Sub-List II.*
- Substances classified with hazard classes EUH380/EUH381 (Endocrine disruption for human health, ED HH 1 or ED HH 2) and EUH340/EUH341 (Endocrine disruption for the environment, ED ENV 1 or ED ENV 2) according to lastly proposed revision of CLP regulation.
- Halogenated organic compounds, such as short-chain chlorinated paraffins (C10-C13), medium-chain chlorinated paraffins (C14-C17) and halogenated flame retardants, with the following exemptions:
  - Halogenated organic pigments that comply with the Council of Europe recommendation "Resolution AP (89) 1 on the use of colorants in plastic materials coming into contact with food", point 2.5.
- Per- and polyfluoroalkyl substances (PFASs), e.g., PFOA and PFOS
- Butylhydroxytoluene (BHT, CAS No. 128-37-0)
- Bisphenols and bisphenol derivatives
  - Bisphenol A used in the production of epoxy acrylate is not covered by the requirement.
  - Assessment of regulatory needs: Bisphenols. ECHA – 16 December 2021: Section 2.1: Bisphenols for which further EU RRM is proposed – restriction  
<https://echa.europa.eu/documents/10162/c2a8b29d-0e2d-7df8-dac1-2433e2477b02>
- Organotin compounds
- APEO (alkylphenol ethoxylates) and APD (alkylphenol derivatives/alkylphenols)
  - Alkylphenol derivatives are defined as substances that release alkylphenols when they break down.
  - An exemption is made for sterically hindered phenolic antioxidants with molecular weight (MW) > 600 g/mole.
- Phthalates
  - Phthalates are defined as esters of 1,2-benzenedicarboxylic acid (orthophthalic acid).
- Pigments, dyes and other additives based on lead, tin, cadmium, chromium VI and mercury, and their compounds.

- Nanomaterials and nanoparticles
  - Nanomaterials/-particles are defined according to the EU Commission Recommendation on the Definition of Nanomaterial (2022/C 229/01). Pigments are exempted from the requirement.
- ☒ A declaration from the manufacturer/supplier of the additive, in accordance with Appendix 5.
- ☒ A safety data sheet for the additive in compliance with current European legislation (Annex II of REACH, Regulation (EC) No. 1907/2006).

## Background

The requirement covers ingoing substances in additives that are added to the polymer raw material in the master batch or compound. Substances that arise from the actual polymer production are thus not covered by this requirement. Recycled plastic raw materials are counted as polymer raw materials, where additives that are added to a new master batch or compound are covered by requirements.

See background to requirement O26 and O28.

### *Nanoparticles*

Nanoparticles are not desirable in ecolabelled products. These include nanometals such as nano silver, nanogold and nano copper. Nanometals such as nano silver and nano copper are a particular problem as they are present in many products for their antibacterial effect. See more information in the chapter 4.6.1 Chemicals.

A nanomaterial is a natural, incidental, or purposely manufactured material containing particles, in an unbound state or as an aggregate or as an agglomerate and where, for at least 50% of the particles in the number size distribution, one or more external dimensions is in the size range 1-100 nm\*. It should be noted that Nordic Ecolabelling does not require a test for all raw materials in terms of nanoparticles. The requirement needs a declaration from the raw material supplier for raw materials that are not covered by the exemption. The declaration must state that the raw material does not contain nanomaterial, as defined in the requirement.

## 4.5.5 Materials based on recycled composite

The requirements in this chapter concern floor coverings and flooring underlays containing recycled composite material. The recycled composite material needs only to comply with the requirements in this section 4.5.5.

### O21 Recycled composite

The recycled composite material must meet the following requirements:

- The ingoing materials and suppliers of the recycled composite material must be stated.
- All recycled composite material must already be a composite. It is not allowed to produce new composite material by mixing pure fractions of different materials, e.g., wood and plastic.

- The composite material must consist of 100% by weight of recycled material. 50% by weight must be post-consumer recycled.
- ☒ Declaration from the producer of the recycled composite material in line with the requirements above.

## Background

The requirement has been changed after the consultation period to clarify that only material based on recycled composite is covered by the criteria. In the consultation version of the criteria wood-plastic composite (WPC) was added as a new material, but the intention was that only recycled material that is already a composite material should be included in the criteria. Materials that are produced by mixing pure fractions of different materials, e.g., wood and plastic, should not be covered by the criteria. This type of material is not allowed mainly since the constituent materials cannot be separated in a recycling process. WPC is also not a very common material used in floor coverings and flooring underlays today. However, new types of products based on materials that are already composites are introduced on the market. The intention is that this type of product should be able to be Nordic Swan Ecolabelled if all requirements in the criteria are met. Composite materials as e.g., composite packaging can be a difficult material to recycle since they consist of different materials. The material is normally sent to incineration. This type of material gets a new area of use when included in a product with long technical lifetime.

## O22 Recycled composite - Additives - Prohibited substances

Additives used during manufacturing of material based on recycled composite (e.g., pigments, UV-stabilisers and bonding agents) must not be classified nor categorised according to the list below.

- Substances on the Candidate List
  - The Candidate List can be found on the ECHA website: <http://echa.europa.eu/candidate-list-table>
  - Exemption applies to melamine (CAS No. 108-78-1)
  - D4 (CAS No. 556-67-2), D5 (CAS No. 541-02-6) or D6 (CAS No. 540-97-6) must only be included in the form of residues from raw material production and are allowed in concentrations up to 1000 ppm each in the silicone raw material.
- CMR substances - Carcinogenic, Germ cell mutagenicity, Reproductive toxicity category 1A or B or category 2 (including all combinations of stated exposure route and stated specific effect)
  - An exemption is made for titanium dioxide (CAS No. 13463-67-7) classified H351
  - An exemption is made for 1,1,1-Trimethylolpropane (TMP, CAS No. 77-99-6) classified H361
- Substances that have been judged in the EU to be PBT (Persistent, Bioaccumulative and Toxic) or vPvB (very Persistent and very Bioaccumulative)
  - PBT and vPvB in accordance with the criteria in Annex XIII of REACH
- Substances classified with hazard classes EUH440 (Persistent, Bioaccumulative and Toxic properties, PBT), EUH441 (Very Persistent, Very Bioaccumulative properties, vPvB), EUH450 (Persistent, Mobile and Toxic properties, PMT and EUH451 (Very Persistent, Very Mobile

properties, vPvM) according to lastly proposed revision of CLP regulation.

- Endocrine disruptors: Substances on the EU member state initiative “Endocrine Disruptor Lists”, List I, List II and List III, see following links:

*List I:* <https://edlists.org/the-ed-lists/list-i-substances-identified-as-endocrine-disruptors-by-the-eu>

*List II:* <https://edlists.org/the-ed-lists/list-ii-substances-under-eu-investigation-endocrine-disruption>

*List III:* <https://edlists.org/the-ed-lists/list-iii-substances-identified-as-endocrine-disruptors-by-participating-national-authorities>

*Substances that are transferred to one of the corresponding sub-lists “Substances no longer on list” and that no longer feature on Lists I–III are not prohibited. However, this does not apply to the substances listed in Sub-List II that were evaluated on the basis of regulations or directives that do not have provisions for identifying endocrine disruptors (e.g., the Cosmetics Regulation). These substances may have endocrine disrupting properties. Nordic Ecolabelling will assess these substances on a case-by-case basis, based on the background information provided in Sub-List II.*

- Substances classified with hazard classes EUH380/EUH381 (Endocrine disruption for human health, ED HH 1 or ED HH 2) and EUH340/EUH341 (Endocrine disruption for the environment, ED ENV 1 or ED ENV 2) according to lastly proposed revision of CLP regulation.
- Halogenated organic compounds, such as short-chain chlorinated paraffins (C10-C13), medium-chain chlorinated paraffins (C14-C17) and halogenated flame retardants, with the following exemptions:
  - Halogenated organic pigments that comply with the Council of Europe recommendation "Resolution AP (89) 1 on the use of colorants in plastic materials coming into contact with food", point 2.5.
- Per- and polyfluoroalkyl substances (PFASs), e.g., PFOA and PFOS
- Butylhydroxytoluene (BHT, CAS No. 128-37-0)
- Bisphenols and bisphenol derivatives
  - Bisphenol A used in the production of epoxy acrylate is not covered by the requirement.
  - Assessment of regulatory needs: Bisphenols. ECHA – 16 December 2021: Section 2.1: Bisphenols for which further EU RRM is proposed – restriction <https://echa.europa.eu/documents/10162/c2a8b29d-0e2d-7df8-dac1-2433e2477b02>
- Organotin compounds
- APEO (alkylphenol ethoxylates) and APD (alkylphenol derivatives/alkylphenols)
  - Alkylphenol derivatives are defined as substances that release alkylphenols when they break down.
  - An exemption is made for sterically hindered phenolic antioxidants with molecular weight (MW) > 600 g/mole.
- Phthalates
  - Phthalates are defined as esters of 1,2-benzenedicarboxylic acid (orthophthalic acid).

- Pigments, dyes and other additives based on lead, tin, cadmium, chromium VI and mercury, and their compounds.
  - Nanomaterials and nanoparticles
    - Nanomaterials/-particles are defined according to the EU Commission Recommendation on the Definition of Nanomaterial (2022/C 229/01). Pigments are exempted from the requirement.
- A declaration from the manufacturer of recycled composite material, in accordance with Appendix 5.
- A safety data sheet for the additive in compliance with current European legislation (Annex II of REACH, Regulation (EC) No. 1907/2006).

## Background

If any chemical additives are used during the manufacturing of material based on recycled composite, they must not contain the listed substances. For more information about the chemical substances see chapters 4.5.4 Plastic, rubber and foam and 4.6.1 Chemicals.

### O23 Chemicals in recycled composite

The used recycled composite material must meet one of the alternatives below.

- a) The composite material that is recycled must come from food contact approved materials (e.g., multi-material/layer food packaging). Please note that recycled composite material that has undergone any recycling process approved by FDA or EFSA may not be used.
- b) The used recycled composite material must not contain the following substances:
  - halogenated flame retardants
  - cadmium
  - lead
  - mercury
  - chromium IV
  - arsenic
  - phthalates
  - polycyclic aromatic hydrocarbons (Benzo[A]Pyrene, Benzo[E]Pyrene, Benzo[A]Anthracene, Dibenzo[A,H]Anthracene, Benzo[B]Fluoranthene, Benzo[J]Fluoranthene, Benzo[K]Fluoranthene, Chrysene)

Impurities up to 100 ppm are permitted.

*\*See section 4.2 Definitions for more information.*

*The requirements for analysis laboratory and test methods are stated in Appendix 1.*

- Declaration from the supplier of recycled composite stating that the material comes from approved food contact materials.
- A test report (XRF, X-ray fluorescence, GC-MS or equivalent method) from the supplier of the recycled composite material showing compliance with the requirement. Alternatively, the requirement can be documented with traceability to the source to substantiate that these substances are not included.

## Background

Nordic Ecolabelling wants to support the use of recycled material, but it is important to not circulate substances hazardous to the environment or health. The material used in recycled composite must either be allowed for food contact or be tested. If the material is allowed for food contact, it is guaranteed that the materials have met strict requirements for content of hazardous substances. Nordic Ecolabelling does not consider it as down cycling to use recycled composite material that is allowed for food contact. This material is hard to recycle, and it is considered positive that the material gets a new area of use and is used in a product with long technical lifetime. Today it is not possible to make new composite material allowed for food contact from this material.

## 4.6 Production processes

### 4.6.1 Chemicals

#### Introduction to chemical requirements

The requirements in this chapter apply to chemical products used in the production/assembly of the Nordic Swan Ecolabelled floor coverings or flooring underlays, such as for example adhesives, resins, sealants, or waxes, as well as lacquers, oils, paints, stains or fillers. The requirements also apply to chemicals used at the production site of subcontractors manufacturing finished layers/elements such as manufactured board and backing foam.

*Lamination (thin layer of laminate < 2 mm, including melamine) on another panel is not considered to be surface treatment. For a wood-based panel with laminate, both elements must fulfil the requirements for the relevant panel type individually, i.e., the wood-based panel and laminate must both meet the requirements for chemicals.*

Chemical products used in the manufacture of paper, and to print patterns on the decor paper, are not covered by the requirements. Auxiliary substances such as lubricants and detergents are also not covered by the requirements.

Requirements specific for surface treatment are presented in chapter 4.6.2.

#### Definitions

The requirements in the criteria document apply to all ingoing substances in the chemical product. Impurities are not regarded as ingoing substances and are therefore exempted from the requirements. Ingoing substances and impurities are defined as below, unless otherwise stated.

- **Ingoing substances:** All substances in the product, including additives (e.g. preservatives and stabilisers) in the raw materials. Substances known to be released from ingoing substances (e.g., formaldehyde, arylamine, in situ-generated preservatives) are also regarded as ingoing substances.
- **Impurities:** Residues from production, incl. raw material production, which remain in the chemical product at concentrations below 1000 ppm (0.1000% by weight). Examples of impurities are reagent residue incl. residues of monomers, catalysts, by-products, “scavengers” (i.e., chemicals used to

eliminate/minimise undesirable substances), cleaning agents for production equipment and “carry-over” from other/previous production lines.

#### O24 Antibacterial substances

Chemical products and nanomaterials\* with antibacterial or disinfectant properties must not be added during production or during surface treatment process. In addition, they must not be added to the finished product nor to finished ingoing elements (e.g., HDF or backing foam).

The term antibacterial means chemical products that prevent or inhibit growth of microorganisms, such as bacteria or fungi. Silver ions, silver nanoparticles, gold nanoparticles and copper nanoparticles are classed as antibacterial agents.

*The requirement does not apply to preservatives used to preserve the chemical product, so-called in-can preservatives.*

*\* Nanomaterials/-particles are defined according to the EU Commission Recommendation on the Definition of Nanomaterial (2022/C 229/01).*

- Declaration from the manufacturer of the product that no chemical products and nanomaterials with antibacterial or disinfecting properties have been added during production or to the finished product. Appendix 2 can be used.
- Declaration from the manufacturer/supplier that the chemical product does not contain nanomaterials with antibacterial or disinfecting properties, in accordance with Appendix 6.

### Background

Products treated with antibacterial agents are commonly marketed as preventing bacteria formation, growth and odours. Antibacterial treatment is often unnecessary and should be used with care as the substances can be harmful to health and the environment, and they risk leading to increased antibiotic resistance. For the background to nanomaterials, see the requirement concerning nanomaterials.

#### O25 Classification of chemical products

Chemical products, including surface treatments, used in the production of the Nordic Swan Ecolabelled product must not be classified in accordance with the table below:

CLP Regulation 1272/2008		
Hazard statement	Hazard class and category	Hazard code
Toxic to the environment*	Aquatic Acute 1	H400
	Aquatic Chronic 1	H410
	Aquatic Chronic 2	H411
	Ozone	H420
Acute toxicity	Acute Tox 1 or 2	H300
	Acute Tox 1 or 2	H310
	Acute Tox 1 or 2	H330
	Acute Tox 3	H301
	Acute Tox 3	H311
	Acute Tox 3	H331
Specific target organ toxicity – single exposure/repeated exposure	STOT SE 1	H370
	STOT RE 1	H372
Carcinogenic <sup>1</sup>	Carc. 1A or 1B	H350
	Carc. 2	H351

Germ cell mutagenic <sup>1</sup>	Mut. 1A or 1B Mut. 2	H340 H341
Reproductive toxicity <sup>1</sup>	Repr. 1A or 1B Repr. 2 Lact.	H360 H361 H362

<sup>1</sup> Including all combinations of stated exposure route and stated specific effect. For example, H350 also covers the classification H350i.

Note that responsibility for correct classification lies with the manufacturer.

Exemptions apply for:

- Classification H351 for adhesive products containing methylene diphenyl diisocyanate (MDI). Isocyanates used in the production of polyurethane material such as polyurethane foam are regulated in separate requirement O36.
  - Classifications H350, H341, H301, H311 and H331 for adhesive products and resins containing formaldehyde (CAS no. 50-00-0). Formaldehyde emissions are regulated in requirements O31 and O41.
  - Classifications H341, H301 and H331 for resins containing a maximum of 10% by weight of phenol (CAS no. 108-95-2).
  - Classifications H301, H311, H331 and H370 for resins containing a maximum of 10% by weight of methanol (CAS no. 67-56-1).
  - Classifications H351 and H361 for resins containing melamine (CAS no. 108-78-1).
  - UV curing surface treatment products classified as environmentally hazardous if UV curing surface treatment products are applied to the material during a controlled closed process where no discharge to recipient takes place. Spills and residual waste (e.g., residues from cleaning) must be collected in containers that are approved for hazardous waste and handled by a waste contractor.
- A declaration from the chemical manufacturer or supplier, in accordance with Appendix 6.
- A safety data sheet for the product in compliance with current European legislation (Annex II of REACH, Regulation (EC) No. 1907/2006).
- Exemption for UV curing products: Description of the process and how waste and residual waste are handled, including information about who receives the wastes.

## Background

Nordic Ecolabelling is generally committed to restricting the use of chemicals that are harmful to health and the environment, and the classification requirement prohibits the products of highest concern.

### Exemptions:

As in previous generation, an exemption is given for accelerators in linoleum flooring production from the classification H400 and H410 up to 1 percent of the linoleum, as alternative accelerators without such classifications are not available at the time being.

Similarly, an exemption for adhesive products containing methylene diphenyl diisocyanate (MDI) is kept. There are currently no substitute products that are

widely available in the market. Hazard code H373 is no longer exempted because it is not anymore forbidden hazard code in the requirement.

The exemption for adhesives and resins containing formaldehyde is only granted if later requirements O31 and O41 concerning the content of free formaldehyde in adhesives and emissions from the finished product are fulfilled.

Resins containing phenol, formaldehyde, methanol and melamine are used in the production of several types of laminates to impregnate the paper. Since it is not possible to produce laminate without these resins, an exemption is made for these substances. A maximum of 10% by weight of phenol and methanol is permitted in the finished resin – the same limit value as was used in the previous generation of the criteria. To ensure that the resins have hardened properly, a subsequent requirement is made concerning emissions from the laminate in its finished form.

The exemption for melamine was introduced during the validity period of the previous criteria, since at that time several suppliers began to self-classify it as H361 (Repr. 2). At the end of 2020, ECHA's Risk Assessment Committee (RAC) also agreed that melamine should be given the harmonized classifications H351 (Carc. 2) and H373 (STOT RE 2). The harmonised classifications will become binding on 23 November 2023. The classification H361 will not be a harmonized classification, but there may still be producers who use this self-classification alongside the harmonized classifications once they come into effect. Nordic Ecolabelling gives an exemption for both the classifications H351 and H361, as there is no substance that can replace melamine at this moment in time. Hazard code H373 is no longer exempted because it is not anymore forbidden hazard code in the requirement.

There is an exemption for UV curing surface treatment products that are classified as environmentally hazardous. UV products have several advantages as they provide a durable surface and contain a low amount of solvents. Later requirements are placed on the amount of VOC applied, which promotes water-based UV products.

UV products contain acrylates, and more and more acrylates are being classified as environmentally hazardous or given stricter classifications. Acrylates and photo initiators are two vital components for UV products to cure. The acrylates change properties in the hardening and bind to the surface coating, so they do not pose an environmental hazard in the finished product. Setting requirements on e.g., the maximum amount of environmentally hazardous substances applied means that only UV products with a lower concentration of acrylates would meet the requirement. This has negative consequences as it leads to longer curing time and more energy-intensive curing. A surface that has not hardened also becomes less resistant and thus offers poorer quality.

## O26 Classification of ingoing substances

Ingoing substances in the chemical product used in production must not have the classifications in the table below.

CLP Regulation 1272/2008		
Hazard statement	Hazard class and category	Hazard code
Carcinogenic <sup>1</sup>	Carc. 1A or 1B Carc. 2	H350 H351
Germ cell mutagenic <sup>1</sup>	Mut. 1A or 1B Mut. 2	H340 H341
Reproductive toxicity <sup>1</sup>	Repr. 1A or 1B Repr. 2 Lact.	H360 H361 H362
Endocrine disruption for human health <sup>2</sup>	ED HH 1 ED HH 2	EUH380 EUH381
Endocrine disruption for the environment <sup>2</sup>	ED ENV 1 ED ENV 2	EUH430 EUH431
Persistent, Bioaccumulative and Toxic properties <sup>2</sup> Very Persistent, Very Bioaccumulative properties <sup>2</sup>	PBT vPvB	EUH440 EUH441
Persistent, Mobile and Toxic properties Very Persistent, Very Mobile properties	PMT vPvM	EUH450 EUH451

<sup>1</sup> Including all combinations of stated exposure route and stated specific effect.  
For example, H350 also covers the classification H350i.

<sup>2</sup> See also requirement O28 for additional requirements on potential or identified endocrine disruptors and PBT/vPvB substances.

For two-component products it is the added ingredients in the separate components that shall comply with the requirement. Alternatively, if it can be documented that protective equipment was worn when the hardener was mixed with the paint/varnish and the finished two-component product was applied in a closed system, the requirement may apply to the hardened product.

Exemptions apply for:

- Photo initiators classified H351, H341 or H361
- Chemical products containing methylene diphenyl diisocyanate (MDI) classified as H351.
- Adhesive and resin containing formaldehyde (CAS no. 50-00-0) classified as H350 and H341. Formaldehyde emissions are regulated in requirements O31 and O41.
- Resin containing maximum 10% by weight of phenol (CAS no. 108-95-2) classified as H341.
- Resin containing melamine (CAS no. 108-78-1) classified as H351 and H361.
- Titanium dioxide (CAS no. 13463-67-7) classified as H351.
- 1,1,1-Trimethylolpropane (TMP, CAS no. 77-99-6) classified as H361.
- VAH (volatile aromatic compounds) in chemical products. VAH content is regulated in requirements O30 and O34.

- A declaration from the chemical manufacturer or supplier, in accordance with Appendix 6.
- A safety data sheet for the product in compliance with current European legislation (Annex II of REACH, Regulation (EC) No. 1907/2006).
- Exemption for two-component products: description of the application system and how employees are protected from exposure and an appendix 6.

## Background

A ban on CMR Category 2 substances has been added to the requirement. Nordic Ecolabelling would like to restrict the use of substances that are carcinogenic, mutagenic and toxic for reproduction (CMR) to the greatest extent possible. This requirement now represents a further restriction on the classification requirement since it applies to ongoing substances in the chemical product.

An exemption has been made for photo initiators classified with H341, H351, or H361. Photo initiators are compounds that produce radicals when exposed to UV light. Then, these react with monomers and/or oligomers to initiate polymer chain growth. They are essential ingredients of all "modern" UV-curable adhesives, and the industry has not yet found substances that can replace them.

Exemptions are also needed in this requirement for methylene diphenyl diisocyanate (MDI), formaldehyde, and melamine. See more background about this in requirement O6 Classification of chemical products.

In addition, there are exemptions for titanium dioxide (CAS no. 13463-67-7) and 1,1,1-Trimethylolpropane (TMP, CAS no. 77-99-6). Titanium dioxide is a white pigment that is used in many different types of product. 1,1,1-Trimethylolpropane (TMP) is used to coat titanium dioxide to make the titanium dioxide particles disperse more easily. About 90% of all titanium dioxide is dispersed with TMP. There are currently no replacement substances for titanium dioxide and TMP.

The Nordic Swan Ecolabel has included the new CLP classifications to align with the European Green Deal's goal of a toxic-free environment. This inclusion reflects the need to establish hazard identification for endocrine disruptors and addresses criteria for environmental toxicity, persistency, mobility and bioaccumulation. By incorporating these classifications, Nordic Swan Ecolabel ensures that the criteria relate to up-to-date scientific understanding and regulatory compliance. Additionally, the inclusion of PMT and vPvM substances is crucial due to their persistence, mobility and potential impact on water quality. The Nordic Swan Ecolabel aims for comprehensive hazard identification and protection of the environment and human health.

An exemption has also been reintroduced for two-component UV products if it can be documented that workers are not exposed (e.g., by using safety equipment when mixing or that the mixing/curing takes place automatically without exposure of the workers and that the application of the finished two-component system is done in a closed system). Nordic Ecolabelling generally wants to limit the use of chemicals with these properties as much as possible, but in some cases, it is difficult to find good substitutes. As these are industrial processes that take place under controlled conditions, the worker and the consumer will not be exposed to these substances.

An exemption to volatile aromatic hydrocarbons (VAH) in chemical products have been granted with conditions that they fulfil the requirements O30/O34 set on VOC (including VAH) content. VAH are volatile organic compounds where one or more benzene rings are contained within the molecule, e.g. toluene, benzene and xylene. VAHs are very stable and have a specific impact on the environment and human health, including damage to DNA. Exposure to these products should be

minimised. For this reason, no more than 1% by weight is permitted in the chemical product according to requirement O30.

## O27 Preservatives

The content of preservatives in the chemical product must meet the following limit values:

Preservative	Limit value
Bronopol (CAS 52-51-7)	≤ 500 ppm (0.05% by weight)
IPBC (iodopropynyl butylcarbamate, CAS 55406-53-6)	≤ 2000 ppm (0.20% by weight)
Mixture (3:1) of CMIT/MIT (5-chloro-2-methyl-4-isothiazolin-3-one / 2-methyl-2H-isothiazolin-3-one, CAS 55965-84-9)	≤ 15 ppm (0.0015 % by weight)
MIT (2-methyl-2H-isothiazol-3-one, CAS 2682-20-4)	≤ 200 ppm (0.02 % by weight)
Total amount of isothiazolinones	≤ 500 ppm (0.05% by weight).

- ☒ A declaration from the chemical manufacturer or supplier, in accordance with Appendix 6.
- ☒ A safety data sheet for the product in compliance with current European legislation (Annex II of REACH, Regulation (EC) No. 1907/2006).

## Background

The content of the preservatives bronopol, IPBC, CMIT/MIT and MIT is restricted via specific limit values. The content of the total amount of isothiazolinones is also limited. IPBC is a fungicide that has become more commonly used and the limit value is the same as in Nordic Ecolabelling's Criteria for Chemical building products. Water-based paints and adhesives may contain the preservative bronopol and it is difficult to find substitutes. A limited amount of bronopol is therefore permitted although it is classified as a substance of concern and hazardous to the environment. Isothiazolinones are used as a preservative in many water-based products, where they act as fungicides, biocides and algal growth inhibitors. They are toxic to aquatic organisms and can cause varying degrees of allergic reactions. It has proved difficult to avoid the use of these preservatives in water-based products, which is what Nordic Ecolabelling's criteria for chemicals indirectly promote. Preservatives also play an important role in ensuring the shelf-life of the products before they are used. Alternative preservatives to isothiazolinones include formaldehyde and/or formaldehyde-releasing substances, which are carcinogenic. In this respect, isothiazolinone and CMIT/MIT are better, even though they also exhibit hazardous properties. To limit the use of these substances as much as possible, the amount of the substances is restricted.

## O28 Prohibited substances

The chemical product used in production must not contain the following substances:

- Substances on the Candidate List
  - The Candidate List can be found on the ECHA website: <http://echa.europa.eu/candidate-list-table>
  - Exemption applies to melamine (CAS No. 108-78-1)
  - D4 (CAS No. 556-67-2), D5 (CAS No. 541-02-6) or D6 (CAS No. 540-97-6) must only be included in the form of residues from raw

material production and are allowed in concentrations up to 1000 ppm each in the silicone raw material.

- Substances that have been judged in the EU to be PBT (Persistent, Bioaccumulative and Toxic) or vPvB (very Persistent and very Bioaccumulative)
  - PBT and vPvB in accordance with the criteria in Annex XIII of REACH
- Endocrine disruptors: Substances on the EU member state initiative “Endocrine Disruptor Lists”, List I, List II and List III, see following links:

*List I:* <https://edlists.org/the-ed-lists/list-i-substances-identified-as-endocrine-disruptors-by-the-eu>

*List II:* <https://edlists.org/the-ed-lists/list-ii-substances-under-eu-investigation-endocrine-disruption>

*List III:* <https://edlists.org/the-ed-lists/list-iii-substances-identified-as-endocrine-disruptors-by-participating-national-authorities>

*Substances that are transferred to one of the corresponding sub-lists “Substances no longer on list” and that no longer feature on Lists I–III are not prohibited. However, this does not apply to the substances listed in Sub-List II that were evaluated on the basis of regulations or directives that do not have provisions for identifying endocrine disruptors (e.g., the Cosmetics Regulation). These substances may have endocrine disrupting properties. Nordic Ecolabelling will assess these substances on a case-by-case basis, based on the background information provided in Sub-List II.*

- Halogenated organic compounds, such as short-chain chlorinated paraffins (C10-C13), medium-chain chlorinated paraffins (C14-C17)
  - Halogenated organic pigments that comply with the Council of Europe recommendation "Resolution AP (89) 1 on the use of colorants in plastic materials coming into contact with food", point 2.5.
  - Exemptions apply for bronopol, IPBC, MIT and CMIT/MIT (3:1). These are addressed in a separate requirement, see requirement 7.
  - Exemption applies for halogenated epoxy acrylate used in UV curing products.
- Per- and polyfluoroalkyl substances (PFASs), e.g., PFOA and PFOS
- Butylhydroxytoluene (BHT, CAS No. 128-37-0)
  - An exemption is made for BHT that is included in UV curing chemical products. If BHT receives a harmonised classification that means the substance does not meet the requirements anymore and the exemption will be removed.
- Aziridine and polyaziridines
  - An exemption is made for aziridines/polyaziridines, if the substance is not classified as carcinogenic, mutagenic or reprotoxic from any manufacturer or in ECHA
- Bisphenols and bisphenol derivatives
  - Bisphenol A used in the production of epoxy acrylate is not covered by the requirement.
  - Assessment of regulatory needs: Bisphenols. ECHA – 16 December 2021: Section 2.1: Bisphenols for which further EU

RRM is proposed – restriction

<https://echa.europa.eu/documents/10162/c2a8b29d-0e2d-7df8-dac1-2433e2477b02>

- Organotin compounds
  - APEO (alkylphenol ethoxylates) and APD (alkylphenol derivatives/alkylphenols)
    - Alkylphenol derivatives are defined as substances that release alkylphenols when they break down.
    - An exemption is made for sterically hindered phenolic antioxidants with molecular weight (MW) > 600 g/mole.
  - Phthalates
    - Phthalates are esters of 1,2-benzenedicarboxylic acid (orthophthalic acid).
  - Pigments, dyes and additives based on lead, tin, cadmium, chromium VI and mercury, and their compounds.
- A declaration from the chemical manufacturer or supplier, in accordance with Appendix 6.
- A safety data sheet for the product in compliance with current European legislation (Annex II of REACH, Regulation (EC) No. 1907/2006).

## Background

### *Candidate List Substances and PBT, vPvB*

The ban on substances on the Candidate List, substances that are PBT (Persistent, Bioaccumulative and Toxic) and vPvB (very Persistent and very Bioaccumulative) and the ban on substances that are considered to be potential endocrine disruptors in category 1 or 2 on the EU's priority list of substances for further evaluation of their role in endocrine disruption are new in this revision. The Candidate List contains substances of very high concern, so-called SVHC substances. SVHCs (Substances of Very High Concern) meet one or more of these criteria:

- Very harmful to health: carcinogenic, mutagenic, toxic for reproduction (CMR substances, category 1A and 1B), set out in REACH, Article 57 a, b, c
- Very harmful to the environment: persistent, bio-accumulative and toxic (PBT) or very persistent and very bio-accumulative (vPvB), set out in REACH, Article 57 d, e
- Serious effects to human health or the environment on another basis than the groups above, but that give equivalent cause for concern (e.g. endocrine disruptors and inhaled allergens), set out in REACH, Article 57 f.

SVHC may be included on the Candidate List with a view to later inclusion on the Authorisation List. This means that the substance becomes regulated (ban, phasing out or some other form of restriction). Nordic Ecolabelling prohibits Candidate List substances due to their hazardous properties. Other SVHC substances are addressed via bans on the use of PBT and vPvB substances, the classification requirements and a ban on endocrine disruptors.

Siloxanes D4, D5 and D6 are included on the Candidate List of Substances of Very High Concern in REACH. However, an exemption has been added for these siloxanes to make it clear that documentation is required to confirm that the content is below the stated limit value in any silicone used. It is possible to find chemicals containing silicone in use throughout the production chain, for example as softeners. The requirement has thus been reworded since the previous generation of the criteria because it used to only cover finishing, membranes, and laminates.

PBT (and vPvB substances) are substances defined in Annex XIII of REACH, which are generally undesirable in Nordic Swan Ecolabelled products.

#### *Endocrine disruptors:*

Potential endocrine disruptors are substances that can negatively affect the hormonal balance in humans and animals. Hormones control a number of vital processes in the body and are particularly important for development and growth in humans, animals and plants.

Changes in the hormone balance can have adverse effects, with a particular focus on hormones that affect sexual development and reproduction. Several studies have shown effects on animals that are probably due to changes in the hormone balance. Effluent discharges are one of the major sources of the presence and distribution of endocrine disruptors in aquatic ecosystems<sup>34</sup>. Nordic Ecolabelling excludes identified and potential endocrine disruptors listed on the “Endocrine Disruptor Lists” at [www.edlists.org](http://www.edlists.org), which is based on the EU member state initiative. Substances listed in Lists I, II and/or III are excluded.

Licensees are responsible for keeping track of updates to the lists so that their Nordic Swan Ecolabelled products fulfil the requirement throughout the entire validity period of the licence. Nordic Ecolabelling recognises the challenges associated with new substances that are added to Lists II and III. We will evaluate the circumstances and possibly decide on a transition period from case to case.

The requirement applies to substances on the main lists (Lists I, II and III) and not to the corresponding sub-lists called “Substances no longer on list”. Substances that are transferred to one of the sub-lists and that no longer feature on Lists I–III are not prohibited. However, special attention is paid to the substances on List II that have been evaluated under the Cosmetics Regulation, for example, where there are no specific provisions to identify endocrine disruptors. It is still unclear how these substances will be handled at [www.edlists.org](http://www.edlists.org) after the evaluation (safety assessment of the substances included in cosmetics, for example) has been completed. Nordic Ecolabelling will assess the circumstances for the substances on Sub-List II on a case-by-case basis, based on the background information provided in the sub-list. By excluding both identified and prioritised potential endocrine disruptors that are under evaluation, Nordic Ecolabelling ensures a restrictive approach towards endocrine disruptors.

---

<sup>34</sup> Miljøstatus i Norge (2008) (Environmental status in Norway): Endocrine disruptors. <http://www.miljostatus.no/Tema/Kjemikalier/Noen-farlige-kjemikalier/Hormonforstyrrende-stoffer/#D> (dated 26 February 2009).

### *Halogenated organic compounds*

Halogenated organic compounds that contain halogens such as chlorine, bromine, fluorine or iodine must not be present in the chemical products used. This includes halogenated flame retardants, chloroparaffins, perfluoroalkyl compounds and certain organic bleaching chemicals. Halogenated organic compounds have various properties that are not desirable in Nordic Swan Ecolabelled products. They are harmful to human health and the environment, highly toxic to aquatic organisms, carcinogenic or harmful to health in other ways. The halogenated organic compounds do not break down readily in the environment, which increases the risk of harmful effects from the substances. A side reaction can occur during the manufacture of epoxy acrylate which results in a small amount of chlorine remaining inside the molecule. The chlorine that is bound in the molecule is relatively stable and will not react further while polymerisation continues. The ban on ongoing substances in the form of halogenated organic compounds applies to the chlorine because it becomes part of the molecule. The quantity of oligomers is normally below 1000 ppm. According to the manufacturers of UV curing chemical products, however, it is not possible to state an exact quantity. Nordic Ecolabelling does not want to ban epoxy acrylate that is used in UV curing chemical products, as such products have multiple environmental benefits. The chlorine in the molecules is not added intentionally for a specific purpose and is therefore exempted. Bisphenol A is also used in the manufacture of epoxy acrylate. It has thus been made more explicit that Bisphenol A used in this manufacturing process is exempt from the requirement.

### *Per- and polyfluoroalkyl substances (PFAs), e.g., PFOA and PFOS*

Fluorosurfactants and other per- and polyfluoroalkyl substances (PFASs) constitute a group of substances that have harmful properties. Certain per- and polyfluorinated compounds can degrade to the very stable PFOS (perfluorooctane sulphonate) and PFOA (perfluorooctanoic acid) and similar substances. These substances are extremely persistent and are easily absorbed by the body<sup>35</sup>. The substances are found all over the globe, from the large oceans to the Arctic. PFOS have also been found in birds and fish and in their eggs. The substances in this group impact on the biological processes of the body and are suspected to be endocrine disruptors, carcinogenic and to have a negative impact on the human immune system<sup>36</sup>. PFOA, APFO (ammonium pentadecene fluoro octanoate) and certain fluoride acids are on the Candidate List due to their repro-toxicity, as well as PBT. There are new research results showing that shorter chains (2-6 carbon atoms) have been discovered in nature<sup>37</sup>.

### *BHT*

Butylhydroxytoluene (BHT, CAS No. 128-37-0) is new to the list of prohibited substances. BHT does not have an official harmonized classification. BHT is included in the EU member state initiative “Endocrine Disruptor Lists”, List II Substances under evaluation for endocrine disruption under EU legislation. Nordic Ecolabelling introduces an exemption for UV curing chemical products. BHT has an important function in such products and can be difficult to replace. Nordic Ecolabelling does not want to prohibit the use of UV curing chemical products as they have other positive properties such as low VOC content. If BHT receives a harmonized official classification that is not allowed in these criteria, then the exemption is no longer valid.

### *Aziridines and polyaziridines*

Aziridine and polyaziridines are classified as H350 (carcinogenic) and H340 (mutagenic) and are thus included in the ban on CMR substances. However, they are on the list of prohibited substances to make it clear that they are prohibited. The substances were also on the list for generation 6 of the criteria.

### *Bisphenols and bisphenols derivatives*

Several bisphenols with the general bisphenol structure and 'bisphenol derivatives' which have constituents with structural properties common to bisphenols are now prohibited. Based on the potential for widespread use and available information on potential endocrine disruptors, reproductive toxicity and PBT/vPvB properties, 34 substances<sup>38</sup> were identified in need for further regulatory risk management in EU<sup>39</sup>.

### *Organotin compounds*

Organotin compounds are used in biocides and as fungicides in a wide range of consumer products. In the textile industry, they can be found in products such as socks, shoes, and sportswear to prevent odours caused by the breakdown of perspiration. One of the most common organotin compounds is tributyltin (TBT). Several of the tin-organic compounds are banned for selected areas of use through Reach Annex XVII entry 20 and the following three; TBTO, DBTC and DOTE are on the EU Candidate List<sup>40</sup>.

### *Alkylphenols, alkylphenol ethoxylates and/or alkylphenol derivatives*

Alkylphenol ethoxylates (APEO) and/or alkylphenol derivatives (APD) are a group of non-readily degradable surfactants that are proven endocrine disruptors. APEOs may be present in binders, dispersing and thickening agents, siccatives, foam inhibitors, pigment pastes, wax, etc. Alternatives to APEOs are available based on alkyl sulphates, alkyl ether sulphates and alcohol ethoxylates. These are readily biodegradable but also have harmful properties, being toxic to aquatic organisms and some may be bioaccumulative. However, there is an

<sup>38</sup> Assessment of regulatory needs: Bisphenols. ECHA – 16 December 2021: Section 2.1: Bisphenols for which further EU RRM is proposed – restriction <https://echa.europa.eu/documents/10162/c2a8b29d-0e2d-7df8-dac1-2433e2477b02>

<sup>39</sup> [2] Annex XV restriction report <https://echa.europa.eu/documents/10162/450ca46b-493f-fd0c-afec-c3aea39de487>

<sup>40</sup> <https://miljostatus.miljodirektoratet.no/tema/miljogifter/prioriterte-miljogifter/tbt-og-andre-organisketinnforbindelser/>) besøgt 8 august 2019.

environmental gain to be made by substitution since they break down rapidly and the degradation product nonylphenol, with its endocrine-disrupting effects, is avoided.

### *Phthalates*

The ban on phthalates has not been changed. Many phthalates are harmful to the environment and human health and should not be used in ecolabelled products for a variety of reasons. Some phthalates are on the EU's priority list of substances for further evaluation of their role in endocrine disruption, and some have already been identified as endocrine disruptors. Some phthalate compounds are also on the Candidate List. All are there because they are classified as toxic for reproduction. Some are also regulated in Annex XVII of REACH, and many phthalates are on the Danish Environmental Protection Agency's "List of Undesirable Substances" and on the Norwegian Environment Agency's "List of Priority Substances". For precautionary reasons, Nordic Ecolabelling has decided to continue to exclude phthalates as a group.

### *Additives based on lead, tin, cadmium, chromium (VI) and mercury, and their compounds*

Nordic Ecolabelling restricts heavy metals because they are toxic to humans and other organisms, both on land and in the aquatic environment. Mercury, cadmium and lead are toxic to the human nervous system, kidneys and other organs, and the metals can accumulate in living organisms. Chromium (VI) is classified as very toxic, CMR and harmful to the environment.

## **O29 Nanomaterials**

The chemical product must not have nanomaterials\* as ingoing substances (See Definitions). Exemptions are made for:

- Pigments. This exemption does not include pigments added for purposes other than colouring.
- Naturally occurring inorganic fillers\*\*
- Synthetic amorphous silica\*\*\*
- Polymer dispersions

\* *Nanomaterials/-particles are defined according to the EU Commission Recommendation on the Definition of Nanomaterial (2022/C 229/01).*

\*\* *This applies to fillers covered by Annex V item 7 of REACH*

\*\*\* *This applies to non-modified synthetic amorphous silica and surface-treated pyrogenic silica, as long as the silica particles form aggregates or agglomerates in the end product. For surface treated nanoparticles, the surface treatment must meet the chemical requirements in O26 (Classification of ingoing substances) and O28 (Prohibited substances).*

- ☒ A declaration from the chemical manufacturer that the chemical product does not contain any nanomaterial, in accordance with Appendix 6.

## **Background**

Due to the small size and large surface area of nanoparticles, they are usually more reactive and may have different properties than larger particles of the same material. There is concern among public authorities, researchers, environmental organisations, and others about the lack of knowledge regarding the potential

harmful effects on health and the environment<sup>41, 42, 43, 44, 45, 46</sup>. Coatings and other modifications may also alter the properties. Nordic Ecolabelling takes the concerns about nanomaterials seriously and uses the precautionary principle to rule out nanomaterials/particles in the products. Nanomaterials/-particles are defined according to the EU Commission Recommendation on the Definition of Nanomaterial (2022/C 229/01)<sup>47</sup>.

Most nanomaterials on the market today have either been in use for decades, or have recently been manipulated into nanoforms of existing materials<sup>48</sup>. For example, carbon black nanoparticles and amorphous silicon dioxide (SiO<sub>2</sub>) have been used in previous centuries. Titanium dioxide (TiO<sub>2</sub>), has long been used as a dye in bulk form, but is now manufactured as a nanomaterial for other purposes<sup>49</sup>. Other types of engineered nanomaterials are expected to enter the market in the future<sup>50</sup>.

In the construction panel product group, nanomaterials are used, among other things, to impregnate or seal surfaces, in order to create hydrophobic, self-cleaning, and antibacterial surfaces. These effects may, for example, come from the addition of nanometals such as silver, gold and copper or titanium dioxide.

The requirement has the following exemptions:

### *Pigments*

Pigments are finely ground, insoluble particles that are used to give the products a certain colour. There are no substitutes that can perform the function of pigments such as paint dyes, inks, fabric dyes, masterbatch, etc. and many pigments consist entirely or partially of nanoparticles. Therefore, nanosize pigments are exempted. Although clear conclusions on the safety of nanopigments cannot be drawn<sup>51</sup>, release by decomposition of facades is very limited and the nanoparticles are probably mainly embedded in the paint matrix rather than released as individual nanoparticles<sup>52,53</sup>. Paint pigments consist of particles of individual crystals up to aggregates of several crystals. It is generally more effective to use pigments with smaller particles than larger to get the same colour. Inorganic pigments used in the paint industry, which can occur in nanosize, include carbon black and iron oxides<sup>54</sup>. Carbon black used in paints is very finely ground and has a particle size of approximately 10–30 nm<sup>55</sup>. Iron oxide pigments can include only nanosize particles, or only a fraction of the particles may be nano. Inorganic nanopigments are also added to products for a number of purposes other than colouring. Nano-titanium dioxide, for example, is used to provide a self-cleaning effect in paint.

### *Naturally occurring inorganic fillers*

Traditional fillers are permitted. Naturally occurring fillers, e.g. from chalk, marble, dolomite and limestone, are exempted from registration in accordance with Annex V, point 7 of REACH, as long as these fillers are only physically processed (ground, sieved and so on) and not chemically modified. An exemption for inorganic fillers has been added as long as they are covered by Annex V, point 7 of REACH.

### *Synthetic amorphous silica*

Silica plays an important role in coating formulations; this is true for non-surface treated types as well as surface modified types. One key functionality of small particle size silica is rheology modification in, for instance, UV-curable wood coatings (e.g. prevention of sagging of coating films applied on vertical substrates). A second very important functionality is the optimisation of the film properties, like scratch and abrasion resistance. Finally, adjustment of gloss and efficient matting of coating films can also be obtained by the use of silica particles.

The surface-treated and non-surface-treated forms are expected to have the same (eco)toxicological profile because the influence of surface treatment on dissolution rate and solubility which was demonstrated in various in vitro experiments has not resulted in biologically relevant differences in bioavailability and toxicokinetics nor were there significant differences in (eco)toxicological outcomes

<sup>55</sup> Coatings Handbook; Thomas Brock, Michael Groteklaes, Peter Mischke; 2000; p. 128

of representative materials tested in key in vivo studies. None of the recent available data for surface-treated and non-surface-treated SAS gives any evidence for a mechanism of systemic toxicity that may raise concerns with regard to human health or environmental risks.<sup>56</sup>

The synthetic amorphous silica can be manufactured in two ways. One way is the precipitation to receive a precipitated silica and the other way is the fumed synthesis to receive a pyrogenic silica. Since the definitions of “colloidal” may be ambiguous and the substance used is pyrogenic silica, exemption has been edited and is granted only to surface-treated pyrogenic silica.

### *Polymer dispersions*

Polymer dispersions have also been exempted from the requirement. In the follow up report from the EU Commission<sup>57</sup> to the second "Regulatory Review on Nanomaterials" from 2012<sup>58</sup> it is stated that the solid nanomaterials dispersed in a liquid phase (colloidal) shall be considered as nanomaterials according to the EU Commissions recommendation. Nano emulsions are however not covered by the definition. Polymers/monomers can occur in different phases and sizes and is therefore chosen to explicitly mention that polymers are exempted from the definition in paint and varnishes.

## **O30 Volatile organic compounds**

Volatile organic compounds (VOC)\*, including volatile aromatic compounds (VAH), may be present in the chemical product to a maximum of 1% by weight.

In adhesives, volatile organic compounds (VOC) may be present to a maximum of 3% by weight. However, volatile aromatic compounds (VAH) may be to a maximum of 0,1% by weight.

Exemptions:

- Chemicals used for surface treatments are exempted from the requirement and must instead fulfil requirement O34.
- Resin used in the production of laminate is exempted from the requirement provided that the laminate flooring meets the emission requirements O35 and O41.

*\*Volatile organic compounds (VOC) are defined as any organic compound having an initial boiling point less than or equal to 250°C measured at a standard pressure of 101.3 kPa. This definition is the same as in the Paints Directive (2004/42/EC).*

Declaration from the adhesive manufacturer/supplier that the requirement is fulfilled, in accordance with Appendix 6.

## **Background**

Volatile organic compounds (VOC), including VAH, are of particular concern due to their inherent properties. They can be absorbed through the lungs and skin and cause damage to various organs. Prolonged exposure to certain organic

<sup>56</sup> <https://echa.europa.eu/de/registration-dossier/-/registered-dossier/15556>

<sup>57</sup> European commission, COMMISSION STAFF WORKING PAPER, Types and uses of nanomaterials, including safety aspects, Accompanying the [...] second regulatory review of nanomaterials, SWD(2012) 288 final

<sup>58</sup> Communication from the commission to the european parliament, the council and the european economic and social committee, Second Regulatory Review on Nanomaterials, COM(2012) 572 final

solvents can cause chronic damage to the brain and nervous system, while other organic solvents can cause cancer or reproductive damage. Nordic Ecolabelling therefore limits VOC levels in chemical products. Resin used in the production of laminate is exempted from the requirement, but the laminate must meet later requirements for VOC emissions to ensure that the resin cures properly.

### O31 Free formaldehyde

The content of free formaldehyde (from formaldehyde not deliberately added or from formaldehyde-releasing substances) must not exceed 0.02% by weight (200 ppm) in the chemical product.

For adhesive products, up to 0.2% by weight (2000 ppm) of free formaldehyde is permitted. The requirement applies to the pure adhesive before mixing with any hardener.

Resin used in the production of laminate is exempted from the requirement if the laminate fulfils requirement concerning emissions of formaldehyde (see requirement O35 and O41).

- ☒ A declaration from the manufacturer/supplier of the chemical product that the requirement is fulfilled, in accordance with Appendix 6.

## Background

Formaldehyde is a toxic and allergenic substance (H317) that has carcinogenic effects (H351). Some free formaldehyde is permitted as an impurity and in adhesive, as it is difficult to avoid this. The purpose of the requirement is to restrict the content of formaldehyde in products in order to limit formaldehyde emissions. Nordic Ecolabelling does not want to request a specific test for this, because that would be too extensive and costly for each chemical product. Nordic Ecolabelling wants to be able to ask for a test if there is any uncertainty about the declaration.

Most of the formaldehyde present in adhesives occurs as free formaldehyde. However, formaldehyde can also originate from the components in the adhesive (such as preservatives). Adhesives emit formaldehyde during both polymerisation and the curing phase. Free formaldehyde reacts when the adhesive is applied to wood or other components, and when the adhesive has cured/dried formaldehyde can be released through degradation processes. It is possible to control and set requirements for the amount of free formaldehyde in the adhesive, in a mixture or in dried glue, but not for what actually occurs when the adhesive is applied to a surface. This is chiefly because neither the adhesive manufacturer nor Nordic Ecolabelling are able to control or influence the choice of wood/material to which the adhesive is applied.

## 4.6.2 Requirements specific to Surface treatments

### O32 Application method and quantity applied – surface treatment

The following information must be given for each surface treatment system used:

- a) Name of surface treatment product and manufacturer of surface treatment product
- b) Quantity applied (g/m<sup>2</sup>), number of coats and application method(s) used
- c) The following efficiency rates must be used when calculating VOC quantities in subsequent requirements:

- Automated spray with no recycling: 50%
- Automated spray with recycling: 70%
- Spray application, electrostatic: 65%
- Spray application, bell/disk: 80%
- Roller coating: 95%
- Curtain coating: 95%
- Vacuum coating: 95%
- Dipping: 95%
- Rinsing: 95%

*The efficiency rates are standard values. Other efficiency rates may be used if they can be documented.*

- ☒ Description from the performer of the surface treatment of each surface treatment system used, in line with the requirement.

## Background

Information about applied quantities, number of coats and method of application is required to calculate applied quantities of VOCs in subsequent requirements.

### O33 Environmentally harmful chemical products and substances in surface treatments

Chemical products used in surface treatment systems (e.g. fillers, oils, stains, lacquers) must fulfil one of the following two alternatives.

- a) None of the chemical products are classified as environmentally harmful according to the table below or,
- b) The quantity of environmentally harmful substances applied in the surface treatment system may be no more than 60 g/m<sup>2</sup>, calculated in a wet state.

UV-curing surface treatment products are exempted from a) and b) if the requirement O25 is fulfilled.

If alternative b) is used, the formula below must be used first to calculate the amount of environmentally harmful substances in the respective surface treatment product (%):

$$100 \cdot H410 + 10 \cdot H411 + H412$$

*H410 is the concentration of substances classified as H410 in percent.*

*H411 is the concentration of substances classified as H411 in percent.*

*H412 is the concentration of substances classified as H412 in percent.*

All environmentally harmful substances that are present in the unhardened chemical products, and are classified according to the table below, are to be included in the calculation.

Hazard class	Hazard category and hazard phrase in line with CLP Regulation 1272/2008
Toxic to aquatic organisms	Chronic 1 with H410
	Chronic 2 with H411
	Chronic 3 with H412

The quantity of environmentally harmful substances applied in the coating system is then calculated as follows:

$$\text{Applied quantity of respective product (g/m}^2\text{)} \times \frac{\text{Proportion of environmentally harmful substances in product (\%)}}{\text{Surface treatment efficacy (\%)}}$$

*When calculating quantity applied, the same efficacy rates are used as those stated in O32.*

*If information about a substance's harmfulness to the environment (in the form of data concerning toxicity and degradability or toxicity and bioaccumulation) is not available, the substance is treated as a worst case, i.e. as environmentally harmful – H410.*

*For tinting systems, a worst-case calculation is made for the colour with the most tinting paste in the base paint containing the most environmentally harmful substances.*

- ☒ A safety data sheet for all chemical products in compliance with current European legislation (Annex II of REACH, Regulation (EC) No. 1907/2006).
- ☒ Alternative b) requires a declaration from the manufacturer/supplier of the surface treatment product stating the content of environmentally harmful substances. Appendix 6 can be used. For each constituent classified substance, the concentration in the chemical product must be stated as a percentage by weight. Confidential details from the chemical manufacturer in the form of content declarations/formulations can be sent directly to Nordic Ecolabelling.
- ☒ Alternative b) requires details of the number of coats, the application method and the quantity applied per coat, stated as g/m<sup>2</sup> flooring. Appendix 7 can be used.

## Background

The various types of floor covering are often surface treated to ensure a durable, easy to clean surface. Wood flooring in particular is often supplied with a surface treatment to ensure a hard-wearing surface, and thus a long service life for the floor. The surface treatment largely takes the form of water-based lacquers, acid cured lacquers, UV lacquers and oils. Within the lacquers there are primers, sealants, undercoats and topcoats that are used alone or together in systems.

The weighting factors for environmentally harmful substances are drawn from chemicals legislation and are a good way of balancing the different degrees of potential environmental harm: H410 is weighted with a factor of 100 since it is the most environmentally harmful, H411 is weighted with a factor of 10 and H412, which is the least environmentally harmful, is multiplied by a factor of 1, i.e., no weighting is applied.

The classification H400, which is acutely toxic to aquatic organisms (not chronically), ought not to be relevant for products for the surface treatment of floor coverings. This classification is used where there is a clear risk of major concentrated emissions on site or where products for industrial cleaning, decreasing etc. reach the drainage system and/or surface water. The classification H413 (suspected harmful to aquatic organisms) is harmful to such a low extent that it has been excluded from the requirement.

UV products contain acrylates, which are being reclassified as environmentally hazardous or receive stricter classifications. The acrylates change properties in the hardening and bind to the surface coating, so they do not pose an

environmental hazard in the finished product. Without the exemption, only UV products with lower concentration of acrylates would meet the requirement. This has negative consequences as it leads to longer curing time and more energy-intensive curing. A surface that has not hardened becomes less resistant, which makes the Nordic Ecolabel's quality and durability requirements more difficult to meet.

Furthermore, most of the studies behind the reclassifications of acrylates monomers are conducted by individual manufacturers and lead to a so-called "self-classifications". "Self-classifications" are to be opposed to harmonised classifications which are legally binding for all manufacturers in the EU. "Self-classifications", until they become harmonised, can be seen as voluntary scientific contributions. Chemical product manufacturers do not have steerability over these but can choose to bend the rules by buying acrylate monomers from manufacturers not using the same scientific data. In this case, to avoid unfair comparisons between chemical products manufacturers, and because of the arguments previously mentioned, it was suggested to grant an exemption to acrylate monomers in UV curing systems provided they fulfil the more risk-based requirement included in O25 Classification of chemical product.

#### O34 Quantity of applied volatile organic compounds (VOC) in surface treatments

Within each surface treatment system, the total content of volatile organic compounds (VOC), including VAH, in surface treatment products must either:

- a) < 5% by weight in total, or
- b) amount to a maximum of 2 g/m<sup>2</sup> treated surface in total.

The requirement relates to the total VOC in the chemical products with the chemical composition they have in wet form. If the products required dilutions, the calculation is to be based on the content in the dilutive product. When calculating quantity applied, the same efficacy rates are used as those stated in O32.

The applied quantity of VOCs according to alternative b) is calculated using the following formula:

$$\text{Applied quantity (g/m}^2\text{)} \times \frac{\text{Proportion VOC in surface treatment (\%)}}{\text{Surface treatment efficacy (\%)}}$$

- Safety data sheet for each chemical product used in the surface treatment system in compliance with current European legislation (Annex II of REACH, Regulation (EC) No. 1907/2006).
- Declaration from the manufacturer/supplier of the chemical products in the surface treatment system, detailing the amount of VOCs in each product, in accordance with Appendix 6.
- A calculation from the performer of the surface treatment showing that the requirement is met, appendix 7 can be used.

### Background

The reason for this requirement is that VOCs contribute to the formation of ozone and have adverse health effects in the workplace and the indoor environment. It is possible to document the requirement concerning VOC in

surface treatment in two ways – either by measuring or calculating emissions of organic solvents and quantities applied per m<sup>2</sup> surface area (application method).

Application method (g/m<sup>2</sup>) forms the basis for calculating the quantity applied in g/m<sup>2</sup>, before then determining the content of organic solvents and/or environmentally harmful substances based on the application method and content of (e.g. %) organic solvents and environmentally harmful substances. If the combined VOC content in the applied products, within one surface treatment system, is less than 5%, it is not necessary to conduct the calculation in grams per m<sup>2</sup>. The reason for this is that products with such little total VOC content will fulfil the set requirements, and an exemption from the calculation will not reduce the level of environmental protection. It will simply make it easier for both applicants and Nordic Ecolabelling when it comes to processing applications.

### 4.6.3 Occupational hazard

#### O35 Emissions to air from production of laminate

This requirement is automatically fulfilled if the laminate used in the floor covering is Nordic Swan Ecolabelled in accordance with the criteria for Panels and mouldings for interior use, generation 7 or later (see requirement O6).

Laminates produced with resins containing formaldehyde and phenol must adhere to the following hygienic limit values for emissions to air in the workplace (gate to gate at the laminate production site) \*:

- The average value during an 8-hour period must not exceed:
  - 0.3 ppm (0.37 mg/m<sup>3</sup>) for formaldehyde
  - 2 ppm (8 mg/m<sup>3</sup>) for phenol.
- The average value during a reference period of 15 minutes must not exceed:
  - 0.6 ppm (0.74 mg/m<sup>3</sup>) for formaldehyde
  - 4 ppm (16 mg/m<sup>3</sup>) for phenol.

*\* If the legislation in the country in question has lower limit values than those stated in the requirement, the legal limit values must be fulfilled.*

Test report showing compliance with the requirement. The report shall contain information about measurements, sampling programs, measurement methods and measurement frequency. For analysis methods, see Appendix 1.

Alternative documentation showing the legal requirements of the country in which production takes place. If the legislation in the individual country has lower limit values than those stated in the requirement, no further documentation is necessary.

### Background

Laminate consists of kraft paper and decor paper impregnated with resins containing phenol, formaldehyde and other substances. During the manufacturing process for the laminate, before the resin has fully cured, emissions to air of phenol and formaldehyde occur. The aim of the requirement concerning hygienic limit values for emissions to air in the workplace is to ensure that the air is measured and that levels are low. The limit values are at the same level as the legal requirements in Sweden and Germany, for example, and those set out by the EU Scientific Committee on Occupational Exposure Limits (SCOEL).

## O36 Polyurethane

Protective measures must be taken to reduce workers exposure as much as possible when handling isocyanates and, when manufacturing and/or welding polyurethane-based (e.g., thermoplastic polyurethane) floor coverings or flooring underlays.

The Workplace Exposure Limits for air\* concentrations of isocyanates in areas where employees are working without protective equipment are:

- MDI (CAS No. 101-68-8): Average over an 8-hour period must not exceed 0.005 ppm (0.05 mg/m<sup>3</sup>)
- TDI (CAS No. 584-84-9 and 91-08-7): Average over an 8-hour period must not exceed 0.005 ppm (0.04 mg/m<sup>3</sup>)

*\*If the legislation in the individual country has lower limit values than stated in the requirement, it is the limit values of the legislation that must be met.*

☒ A description of the safety measures taken and the statutory Workplace Exposure Limits for isocyanates in the country of manufacture of the polyurethane material. If the statutory limits are the same or more stringent than the threshold limit values in the requirement, no further documentation is required. If the statutory limits are less stringent, a description of how air concentration levels of isocyanates are measured must be submitted, along with a test report showing compliance with the threshold limit values specified in the requirement.

☒ A description of the safety measures taken when manufacturing as well as welding/installing the polyurethane-based product must be provided by the manufacturer.

### Background

Polyurethane is formed through polyaddition between isocyanates and polyol. The isocyanates that are used for the manufacture of polyurethane foam are MDI (CAS No. 101-68-8) and TDI (CAS No. 584-84-9 and 91-08-7). Both these isocyanates are suspected of causing cancer and may cause sensitisation by inhalation and contact with skin. From an occupational health and safety perspective, MDI is slightly better but gives the foam other technical properties and it is therefore not possible to completely replace TDI with MDI. Among other things, MDI gives the foam a higher density.

Polyurethane as a material is harmless, however if it is heated and reaches a certain temperature, it can start releasing isocyanates and it is important to limit worker's exposure to them. Hence, a description of the safety measures taken to minimise employee's exposure at the polyurethane manufacturing plant is required, and the hygiene threshold limit values for TDI and MDI must be observed. The threshold limit values set in this requirement are the same as those in the Norwegian Labour Inspection Authority's Regulations on measures and threshold limit values.<sup>59</sup> It is also required that the polyurethane-based floor covering manufacturer sends a description of the safety measures taken when manufacturing the product and when the installer welds it. Isocyanate compounds may only be used in closed processes were recommended/prescribed occupational and health safety equipment is worn.

<sup>59</sup> <https://www.arbeidstilsynet.no/regelverk/forskrifter/forskrift-om-tiltaks--og-grenseverdier/8/1/>

## 4.6.4 Energy and Waste

### O37 Energy mapping

An energy audit according to standards ISO 50002 or EN 16247-1 or equivalent, and an energy mapping of the floor covering or flooring underlays manufacturing plant must be conducted by a third party, alternatively verified by a third party.

Furthermore, an action plan resulting from the energy mapping/audit and with purpose to reduce energy consumption must be developed by a third party or verified by a third party.

*If a new energy audit and a new energy mapping must be conducted again during the validity of the criteria, new action plans or other up-to-date documents must be sent anew as well. It is the license holder's responsibility to make follow-up plans so that this requirement is always fulfilled.*

- ☒ The energy mapping report and the action plan for the floor covering or flooring underlays manufacturing plant must be sent as well as documentation that they have been done by a third party or alternatively verified by a third party. Documentation created to obtain energy management system certification ISO 50001 can also be sent as an alternative.

### Background

Because the production of flooring is energy intensive, a requirement has been introduced to push the manufacturers towards reducing their energy consumption. Through energy mapping and energy audits, energy action plans can be implemented to identify issues related to low energy efficiency. They allow to set goals that can be considered as proven energy reduction commitments. By working with certifications of the manufacturing plant in accordance with e.g., ISO 50001, or other acknowledged energy assessment standards, the plant is recognized as working with international climate goals to reduce its energy demand and/or implement energy efficient measures by introducing operational changes.

Moreover, requirement O38 energy consumption demands that a certain quantity of data and information is collected. The collection and its verification by both the applicant and the application handler can become time-consuming. An energy mapping performed by a specialised third party allows trustworthy and efficient data extraction, and open possibilities to set more comprehensive energy requirements in the future.

### O38 Energy consumption

An energy calculation is to be made according to the equation below:

$$E = \frac{A}{20} + \left(5 - \frac{B}{3 \text{ (kWh/m}^2\text{)}}\right) + \left(5 - \frac{C}{3 \text{ (kWh/m}^2\text{)}}\right)$$

The E score must reach at least:

- E shall be at least 11.0 for solid wood flooring, parquet flooring, bamboo flooring and cork flooring/underlays.
- E shall be at least 10.0 for laminate flooring and hybrid flooring.
- E shall be at least 9.0 for linoleum flooring, plastic flooring and underlays.

The E score does not have any measurement unit.

The following applies for the individual energy components:

Environmental parameters	Requirement / limit value
A = Proportion of renewable fuel (%)*	Minimum 25%
B = Purchased electricity	Maximum 15 kWh/m <sup>2</sup> per year
C = Fuel consumption	Maximum 15 kWh/m <sup>2</sup> per year

\*Renewable fuel must not be based on palm oil, including by-products, residues and waste fractions from palm (e.g., Palm Fatty Acid Distillate: PFAD).

The requirement for energy consumption includes all the floor covering or flooring underlays manufacturing plant's purchased energy in kWh per m<sup>2</sup> of product produced per year. The unit kWh/m<sup>2</sup> was chosen but it can be converted as follows: 1 kWh = 3.6 MJ.

An indicative list of activities that must be included and may not be included in the calculations of the energy consumption can be seen in in Appendix 8.

Appendix 9 lists the heating values, i.e., energy content, of different fuels. A licence applicant/holder may also use its own specific fuel values.

Manufacturers that sell surplus energy, in the form of electricity, steam or heat, must deduct the quantity sold from the electricity consumption figure, or the fuel consumption figure respectively. Only fuel and electricity that is consumed in the manufacture of the floor coverings or flooring underlays may be included in the calculation.

Renewable electricity generated onsite (from solar PV panels, wind turbine or geothermal powerplant) is not purchased and may be left out from the calculations of B and E. Onsite means on the property or immediate vicinity of the manufacturing site.

- ☒ State which types of fuel have been used in the manufacture of the floor covering over the past year, and which fuels are renewable. In cases biodiesel or bioLPG is used as renewable fuel, it must be documented that it is not based on palm oil nor PFAD. State how much electricity has been used and how much floor covering or flooring underlays (m<sup>2</sup>) has been produced over the past year. Appendix 8 can be used.
- ☒ State if an energy surplus has been deducted from the plant consumption. State how much renewable electricity is generated onsite (e.g., from solar panels, wind turbine and geothermal powerplant). Data from the energy mapping performed by a third party according to requirement O37 can be used. Appendix 8 can be used.
- ☒ Enclose the detailed calculations of A, B, C and E. Examples of calculation can be found in Appendix 10. The energy content of different fuels can be found in Appendix 9.

## Background

The production of floor coverings comprises many steps that can be highly energy demanding and energy consumption is directly linked to the emission of greenhouse gases. Furthermore, whether the energy comes from renewable sources or is of fossil origin can have a great influence on the quantity of emission released into the atmosphere. Increasing the share of renewable energy/fuel used, lowering the overall energy consumption and having an energy efficient production reduces the overall environmental impact of the flooring production by diminishing its contribution to climate change. There is generally high environmental relevance (see RPS analysis) in setting requirements for energy consumption, for both ingoing materials and the final flooring product itself. As the manufacturing processes can differ from a flooring type to another, different limit values to fulfil the energy consumption requirement have been set. This

enables direct energy efficiency comparisons between production lines within each flooring type.

The energy requirement comprises two parts. One part contains requirements for the use of electricity, fuel and renewable fuel. The other sets out a certain score that must be achieved in the energy formula. The energy requirement promotes low energy consumption in terms of electricity and fuel through limit values (the maximum fuel consumption has been tightened from 30 kWh/m<sup>2</sup> to 15 kWh/m<sup>2</sup>), as well as a minimum fixed share of renewable fuels (25%). Renewable fuel is defined as non-fossil fuels (peat is not considered to be renewable). In this requirement, no account is taken to purchased “green electricity”, i.e., renewable electricity traced with for example Guarantees of Origin or RECs (Renewable Energy Certificates). The reason is that Nordic Ecolabelling has not found enough evidence that purchasing green electricity leads to increased amount of renewable electricity in the energy system.<sup>60,61</sup> However, the requirement can be easier to meet if electricity produced from renewable energy is generated on-site.

The formula is designed such that a maximum total “E” is achieved as follows:

$$E = \frac{A}{20} + \left(5 - \frac{B}{3 \text{ (kWh/m}^2\text{)}}\right) + \left(5 - \frac{C}{3 \text{ (kWh/m}^2\text{)}}\right)$$

The E score does not have any unit. The mathematically correct equation can be seen above but has been simplified in the requirement to avoid confusion. Each term/subcomponent may be a maximum of 5. Each subcomponent contributes equally to the total E, making them all equally significant. This means that the lower energy consumption and the higher the proportion of renewable fuel are, the higher the E-score becomes. The functional unit for this product group being 1m<sup>2</sup>, the data that must be reported to calculate factors B and C must have for unit kWh/m<sup>2</sup>.

The table in Appendix 8 clarifies which processes/steps are to be included in the energy consumption calculations. Since the further back in the supply chain the process is, the lesser the steerability becomes, it was decided to exclude all steps coupled to raw material extraction from the calculations. Meaning that energy consumption of processes associated with wood and crops harvesting as well as oil extraction may be disregarded when performing the calculation. Following the same reasoning, processes occurring at the end of the production line such as surface treatment and packaging must be included, as steerability is considerably higher.

For the sake of harmonization, it is required to include the energy consumption to manufacture the main binder in a plastic flooring or the main binder/HDF in a hybrid flooring. The same way it is required to take into consideration the energy consumption to manufacture the HDF in a laminate flooring or the different wood layer in a parquet into the calculations. However, as energy consumption of the manufacture of bought-out parts/layers that stands for less than 5 w% of the final floor covering may not be included in the calculations, energy consumption for the manufacture of structural and decorative papers in laminate flooring may

<sup>60</sup> [Creative accounting: A critical perspective on the market-based method for reporting purchased electricity \(scope 2\) emissions - ScienceDirect](#)

<sup>61</sup> <https://osloeconomics.no/wp-content/uploads/2018/09/Utredning-om-opprinnelsesgarantier-og-varedeklarasjoner-for-strom.-Endelig-rapport.pdf>

be disregarded. Energy consumption in the manufacture of chemical products such as adhesives and lacquers may also be disregarded from the calculations.

Underlays are mostly products made from plastic polymers or renewable material such as cork and that is why, the same E-score limit value as the floor coverings of the same materials has been set.

It is often impossible to separate out energy consumption and ascribe it to a particular floor covering, since it applies to the whole factory. This means that the energy consumption data on which the requirement is based, and which is to be used for licensing is an annual average and is not necessarily the specific energy consumption linked to the particular Nordic Ecolabelled floor covering(s). Consequently, this requirement will be fulfilled only by the best factories in terms of energy consumption/efficiency.

### O39 Handling of waste and production waste

The floor coverings or flooring underlays manufacturer must sort waste at source into the fractions that arise during production, including production waste.

Hazardous waste must be treated and dealt with in accordance with the regulations applicable in the country of manufacture.

Furthermore, a plan for handling waste must be drawn up and must include:

- The different waste fractions,
- Initiatives taken to reduce waste generation and to improve production efficiency,
- As well as a description on how the waste is dealt with (e.g., recycling, landfill and incineration). However, production waste must not be landfilled.

⌚ Requirement is also checked on site.

☒ Declaration of hazardous waste, if applicable, and a statement on how hazardous waste is handled in accordance with the regulations applicable in the country of manufacture. Waste handling plan featuring waste fractions, initiatives taken and how the waste fraction is dealt with. Alternatively, an ISO 14001 certificate for the manufacturing plant and an Eco-Management and Audit Scheme (EMAS) certificate for the company can be sent to show compliance with this requirement.

## Background

The requirement concerning waste management includes requirements for generally good waste management. It is based on legislation in the Nordic countries, which discourages the use of landfill. Environmental and commercial/economic drivers steer companies towards material recovery or energy recovery from the waste, where possible. Hence, the waste requirement is judged to be fit for purpose in its revised form.

To further support/acknowledge manufacturers working with management systems, documentation showing that the plant is certified according to ISO 14001 as well as a certificate attesting that the company follow the Eco-Management and Audit Scheme (EMAS).

## 4.7 Packaging

### O40 Packaging

The requirement applies to disposable packaging used for packaging of the individual product.

The packaging must be able to be recycled in today's recycling systems.

The following materials are prohibited in packaging:

- chlorinated polymers / plastics such as PVC
- metal\*

\* *Exceptions are given for staples.*

- ☒ State the type of material used in the packaging. Declaration from the producer of packaging that it can be recycled according to current systems.
- ☒ Description showing that no disposable packaging is used or declaration from the manufacturer of the product that PVC or metal has not been used in the packaging.

### Background

For a ban on chlorinated plastic, see O5 (PVC is also banned in the product). Nordic Ecolabelling does not want metal to be used for packaging as metal production is associated with a large climate and environmental impact. Exceptions are for any staples that can be used to staple cardboard or plastic together. Cardboard and paper can be recycled, but not all types of plastic can. Examples of plastic types where there are good material recycling systems today are Polyethylene (PE), Polypropylene (PP) and Polyethylene terephthalate (PET). Degradable/compostable plastic cannot be recycled in current systems, which means that e.g. PLA plastic cannot be used.

## 4.8 Use-phase requirements

### 4.8.1 Emission

#### O41 Emissions from floor coverings and flooring underlays

Emissions from floor coverings and underlays must not exceed the limit levels in the tables below.

#### Wood-based products

The tests shall be carried out in accordance with the test method ISO 16000-9 or EN 16516 for TVOC/SVOC/Carcinogenic VOC, and EN 717-1 for formaldehyde. Testing must be done on the final product.

Type of floor covering	TVOC (C6-C16) (mg/m <sup>3</sup> )	SVOC (C16-C23) (mg/m <sup>3</sup> )	Formaldehyde (mg/m <sup>3</sup> )	Carcinogenic VOC in category 1A and 1B (mg/m <sup>3</sup> )
Bamboo flooring, cork flooring/cork tile flooring and cork-based underlays	0,3	0,03	0,06	0,001
Solid wood flooring	0,3	0,03	0,06	0,001
Multi-layer wood flooring and wood veneer flooring	0,3	0,03	0,06	0,001

*Limit value after 28 days according to EN 16516, ISO 16000-9 or EN 717-1. If the limit values in the table are met for a period shorter than 28 days, this is accepted.*

*Other analysis methods than those stated in the requirement may be used, provided that the correlation between the test methods can be verified by an independent third party.*

### Other products

The tests shall be carried out in accordance with the test method ISO 16000-9 or EN 16516 and on the final product.

Type of floor covering	TVOC (C6-C16) (mg/m <sup>3</sup> )	SVOC (C16-C23) (mg/m <sup>3</sup> )	Formaldehyde (mg/m <sup>3</sup> )	Carcinogenic VOC in category 1A and 1B (mg/m <sup>3</sup> )
Multilayer modular flooring, hybrid flooring and other underlays	0,2	0,02	0,01	0,001
Laminate flooring	0,1	0,02	0,03	0,001
Linoleum flooring	0,2	0,03	0,01	0,001
Plastic flooring and plastic underlays	0,1	0,02	0,01	0,001

*Limit value after 28 days according to EN 16516, or ISO 16000-9. If the limit values in the table are met for a period shorter than 28 days, this is accepted.*

*Other analysis methods than those stated in the requirement may be used, provided that the correlation between the test methods can be verified by an independent third party.*

- ☒ Analysis report, including measurement methods, results, and measurement frequency. It must be clearly stated which method/standard that was used, the laboratory that conducted the analysis, and that the analysis laboratory is an independent third party. Please refer to laboratory requirements in Appendix 1.

### Background

The requirement was introduced in the previous generation of the criteria since building materials can have a major impact on the indoor environment of a building. Since underlays are now included in the product group the emissions requirement also applies to underlays.

The requirement states the limits for emissions of TVOC (Total Volatile Organic Compounds), SVOC (Semi Volatile Organic Compounds), formaldehyde and carcinogenic VOC (in line with the EU taxonomy requirements) for different materials used in floorings. In this revision, specific limit values are introduced for hybrid and laminate flooring.

The requirement for formaldehyde emissions from wood-based products are harmonised with the EU Taxonomy requirement. The specified test conditions refer to in Annex XVII to Regulation (EC) No 1907/2006. However, the use of different test standards in relation to the stated emission value of 0,06 mg of formaldehyde per m<sup>3</sup> (correlation between standards) is still being debated. According to consultation comments and dialog with Eurofins<sup>62</sup>, EN 717-1 is the method that follow the parameters. EN 16516 can also be used to show fulfilment

<sup>62</sup> Comparison of formaldehyde concentrations in emission test chambers using EN 717-1 and EN 16516 (CEN/TC 351/WG 2), 2020-07-22

of the limit values since but since this method gives a higher test result this can be considered worst case. According to report on comparison of formaldehyde emissions using EN 717-1 and EN 16516 (footnote 62) the conversion factor for using EN 16516 is 1,6. The German legislation regarding emission of formaldehyde from wood-based panels uses a conversion factor when using EN 16516 on 2.0. The difference in conversion factors off cause have a huge effect when setting a specific limit using EN 16516. Nordic Ecolabelling is closely following the ongoing interpretation debate regarding use of test methods and scientifically proven correlation between the 0,06 mg/m<sup>3</sup> limit and test methods. The EU regulation on formaldehyde (EU 2023/1464)<sup>63</sup> new limit values for furniture and wood-based products are 0.062 mg/m<sup>3</sup>. The test parameters refer to Annex XVII to Regulation (EC) No 1907/2006 as well.

Except for TVOC limit for solid wood and multi-layer wood and wood veneer flooring, all limit values have been tightened. The tightening is based on a review of results from emission testing of Nordic Swan Ecolabelled products, comments from the public consultation and the limit values of other certification schemes like EU Ecolabel and BREEAM-NOR v.6.0. All TVOC, SVOC and formaldehyde limit values are equal to or below the limit values required for building products by BREEAM-NOR v.6.0 Basic level which is their strictest emission level. This means that all Nordic Ecolabelled wood floorings fulfil the emission requirements from the latest standard BREEAM-NOR v.6.0. Some limit values are also stricter than the M1-certification. Indeed, the M1 level is reached if emissions are lower than 0,16 mg/m<sup>3</sup> (re-calculated from 0,2 mg/(m<sup>2</sup>h)). Testing of emissions might be done according to the test method EN 16516, ISO 16000-9 or EN 717-1 as in the previous generation of the criteria. Our license holders are using all different methods. Both EN 16516 and ISO 16000-9 methods are also acceptable within BREEAM-NOR v.6.0.

## 4.8.2 Quality and durability requirements

### O42 Product performance – third-party verification

For products not covered by a harmonised product standard (e.g., flooring underlays) the features and functions for which they are marketed for must be documented. One of the following options must be chosen:

- voluntary CE marking and declaration of performance according to an ETA (European Technical Assessment), or
- the properties of the product can be declared via a corresponding third-party verification of the product's performance. Third-party verification must be approved by Nordic Ecolabelling.

☒ A voluntary CE marking, and declaration of performance must be submitted in accordance with an ETA or other third-party verification of the product's performance.

## Background

Generally, manufacturers producing products covered by a harmonised standard in accordance with the Construction Products Regulation (EU/305/2011) can document the features and functions for which the products are marketed for, with, for instance, an example of CE marking and a declaration of performance. Indeed, laminate, linoleum and plastic flooring must follow the standard EN

<sup>63</sup> <https://eur-lex.europa.eu/legal-content/EN/TXT/PDF/?uri=CELEX:32023R1464>

14041:2004 - Resilient, textile and laminate floor coverings - Essential characteristics. However, wood flooring (solid wood, parquet and veneer) must follow the standard EN 14342:2013 - Wood flooring and parquet — Characteristics, evaluation of conformity and marking.

This requirement ensures that manufacturers producing products (e.g., underlays) which are not covered by a harmonised product standard can document the features and functions for which the products are marketed for, on the basis of standardised test results. General requirements for CE marking can be used as guideline.

### O43 Quality and Durability of floor coverings

Only the requirements associated with the specific type of flooring must be fulfilled.

The floor covering must be tested according to the relevant quality/durability standard(s) mentioned in the table in appendix 11. According to the classification standard from the same table in appendix 11, the floor covering must at least achieve the following use of class named in the table below:

Flooring	Limits
Wood veneer floor covering	— the level of use of class 23 for floorings intended for private use — the level of use of class 32 for floorings intended for commercial use.
Factory lacquer solid and multilayer wood floorings	— the level of use of class 23 for floorings intended for private use and for commercial use (see appendix 12).
Factory oiled, uncoated solid wood and uncoated multilayer wood flooring	
Cork tile floor coverings	— the level of use of class 23 for floorings intended for private use — the level of use of class 32 for floorings intended for commercial use.
Cork floor coverings	
Bamboo floor coverings	— Equilibrium Moisture Content: 8 % at 20 °C and 50 % relative humidity — Resistance to Indentation: ≥ 4 kg/mm <sup>2</sup> for plain and side pressed floor coverings ≥ 9,5 kg/mm <sup>2</sup> for high density floor coverings
Laminate flooring	— the level of use of class 23 for floorings intended for private use — the level of use of class 32 for floorings intended for commercial use.
Linoleum flooring	— the level of use of class 23 for floorings intended for private use — the level of use of class 32 for floorings intended for commercial use.
Plastic flooring	— the level of use of class 23 for floorings intended for private use — the level of use of class 32 for floorings intended for commercial use.
Others (e.g., multilayer Modular floor coverings, hybrid flooring)	— the level of use of class 23 for floorings intended for private use — the level of use of class 32 for floorings intended for commercial use.

Other relevant standards might be accepted if the testing institute is able to provide documentation to show that the chosen test is equivalent and will give approximately the same results.

Testing must be performed by an independent, accredited testing institute. Internal test laboratories can be approved under given conditions, see Appendix 1.

The testing must be carried out in accordance with the applicable version of the standard. If a standard is revised and updated during the period of validity of the license, it is the licensee's responsibility to ensure that the requirements of the new applicable version of the standard are met.

In cases where the floor covering is intended for both private and commercial use, the product must meet the higher requirements, that is the ones that apply to commercial use.

- ☒ Technical data sheet, declaration of performance or other documents where the parameters, the standards/test methods and the level of use of class are clearly stated.
- ☒ A test report showing that relevant requirement levels have been met. It must be clearly stated which method/standard was used, the laboratory that conducted the analysis, and that the analysis laboratory is an independent third party. Other analysis methods than those stated in the requirement may be used, provided that the correlation between test methods can be verified by an independent third party.

## Background

Increasing the service life reduce drastically the contribution from raw material extraction and production phases to the overall environmental impacts of floor covering. Indeed, less resource (oil, water, energy...etc.) is needed if a floor covering must be changed after 20 years, instead of every 2 years. Many parameters can affect the service life of a floor covering and two of them are, of course, the wear resistance of the top layer and the traffic occurring on them. It is worth noticing that the longer the floor covering's service life is, the larger the contribution of the use phase to the total environmental impact becomes (see Circular requirements).

In addition to the standards for general characteristics named in the requirement for CE marking, there are testing methods listed in European/international harmonised standards for the majority of flooring material types. Depending on the results obtained for each relevant parameter to be tested according to the flooring type specific test standard, the floor covering's use class will be determined.

References are made to the latest versions of the standards and test methods. For instance, veneer floorings must be tested according to standard EN 14354. Parquet floorings must be tested according to standard EN 13489. However, because the regular wear resistance test method for parquet considers only the thickness of the wear layer and the wood species used (according to CTBA's classification based on the Brinell hardness test, see appendix 12), it has been deemed relevant to set additional test requirements, notably on the lacquer used. If the parquet is not lacquered (oiled or unfinished), it must be possible to perform sanding and apply a finish if desired. Indeed, to comply with standard EN 13489, a parquet must be capable of undergoing renovation at least twice (see requirement on product information). Overall, it has been difficult to find a complete set of standards ensuring that only the parquet floorings of best quality can be Nordic Ecolabelled. Indeed, manufacturers use their own in-house developed methods coupled with more general measures (e.g., construction stability, cleaning properties and available cleaning products) to guarantee good longevity of their products. That is why, it was deemed relevant to keep thickness of the top layer and harness of the wear layer to ensure good quality and add that the flooring be tested for resistance to chemical agents and its lacquer be tested for its elasticity and against abrasion.

The durability of bamboo floorings is not standardized. In this case, the industry reports the characteristics of the bamboo flooring (test results and test methods) without classifying the flooring. Due to the lack of standards, industry can adapt standards developed for other types of floorings to their necessities (e.g., FprEN 1534) or carrying out their own measurements, leading to different measures that are not comparable. Setting a minimum performance, is therefore, extremely difficult. If there is no harmonised European test standard, such as for bamboo flooring, floor coverings can be tested according to a test method chosen by an independent testing institute with the competence to conduct wear tests on flooring.

The different use classes are listed in the classification standard EN ISO 10874. This way, the use classes give the user a quick overview of the flooring material's durability and suitability for different environments (i.e., different traffic intensity). The use classes are divided into Domestic, Commercial and Light Industrial, with 3-4 intensity levels in each class (see table 2 in Appendix 11).

Nordic Ecolabelling requires that the floor covering at least reaches the use class of 23 if intended to use in private homes or, 32 if used in area with higher traffic.

#### O44 Quality and Durability of flooring underlays

Underlays must follow the standards for testing stated in the latest version of the relevant technical bulletin, and meet the requirements listed in the table below.

Testing must be performed by an independent, accredited testing institute. Internal test laboratories can be approved under given conditions, see Appendix 1.

The testing must be carried out in accordance with the applicable version of the standard or technical bulletin. If a technical bulletin or standard is revised and updated during the period of validity of the license, it is the licensee's responsibility to ensure that the requirements of the new applicable version of the standard or technical bulletin are met.

If the underlay is intended to be used underneath several different types of flooring, only one of the relevant bulletins can be chosen to prove its good performance.

Underlay type	Standards/Technical Bulletin	Requirement level
Underlay materials under wood flooring. (Flooring types EN ISO 14354 and EN ISO 13489)	Technical Bulletin from European Parquet Federation (FEP). <sup>64</sup> The test methods are described in the standard EN 16354 "Laminate floor coverings - Underlays - Specifications, requirements and test methods".	Underlays intended for private use must fulfil the minimum requirements.
Underlay Materials under Laminate Floor Coverings. (Flooring type EN 13329)	Technical Bulletin from European Producers of Laminate Flooring (EPLF). <sup>65</sup> The test methods are described in the standard EN 16354 "Laminate floor coverings - Underlays - Specifications, requirements and test methods".	
Underlay Materials under Multilayer	Technical Bulletin from Multilayer Modular Flooring Association (MMFA). <sup>66</sup>	Underlays intended for commercial use must fulfil the higher requirements.

<sup>64</sup> <https://drive.google.com/file/d/1q82Y5cBEWfVZjumWXdqg9Eh1tE4Vt9R/view>

<sup>65</sup> [https://epif.com/storage/files/tb\\_-\\_epif\\_underlay\\_materials\\_under\\_laminate\\_floor\\_coverings\\_2019-02\\_en.pdf](https://epif.com/storage/files/tb_-_epif_underlay_materials_under_laminate_floor_coverings_2019-02_en.pdf)

<sup>66</sup> [https://mmfa.eu/wp-content/uploads/2020/12/TB1-Underlay-Materials-under-MMF-Floor-Coverings\\_2020-12\\_EN.pdf](https://mmfa.eu/wp-content/uploads/2020/12/TB1-Underlay-Materials-under-MMF-Floor-Coverings_2020-12_EN.pdf)

Modular Floor Coverings. (Flooring types EN 16511).	The test methods are described in the technical bulletin.	
--	---	--

In cases where the underlay product is intended for both private and commercial use, the product must meet the higher requirements, that is the ones that apply to commercial use.

The performance of underlay materials used under other flooring types (e.g., plastic and linoleum floorings) must be tested according to test methods described in a relevant standard or selected by an independent test institute. The selected test method must consider the intended use area of the floor. For instance, corkment underlays must follow the standard EN 12455.

- Technical data sheet, declaration of performance or other documents where the parameters and the standards/test methods are clearly stated.
- A test report showing that relevant requirement levels have been met. It must be clearly stated which method/standard was used, the laboratory that conducted the analysis, and that the analysis laboratory is an independent third party. Other analysis methods than those stated in the requirement may be used, provided that the correlation between test methods can be verified by an independent third party.

## Background

Underlays, or underlayment, are products installed directly underneath the floor covering and intended to enhance the properties of the whole construction (floor covering + underlays). Through different properties such as, vapour barrier or click support, they can extend the service life of the floor covering. They can also improve the consumer's life quality because of their ability to level out irregularities and their intrinsic sound dampening properties.

As it is also important that the underlays is of good quality, a standard including test methods for many different parameters has been developed. This standard is EN 16354 and is intended for underlays used under laminate floorings. However, several trade associations such as EPLF (European Producers of Laminate Flooring), FEP (European Parquet Federation) and MMFA (Multilayer Modular Flooring Association) has created technical bulletins or guidelines on how to test underlays, all based on standard EN 16354 ("Laminate floor coverings - Underlays - Specifications, requirements and test methods"). These technical bulletins all contain a table that state what requirements and which level can be set. Nordic Ecolabelling set the highest requirements on underlays intended to be used in commercial area while underlays used under a consumer's floor need to fulfil the minimum requirements.

However, the choice of underlay can depend, for instance, on the kind of substrate (concrete, wood-based...etc.) on which the underlay and floor is installed. Meaning, there does not have to be a direct correlation between a specific flooring and a specific underlay product. Moreover, not all trade associations have written their own technical bulletin or guideline on underlays. That is why, for underlays that may be used under plastic or linoleum flooring, there is the possibility of testing according to a test method described in a relevant standard or selected by an independent test institute. Corkment

underlays, that are usually used under plastic and linoleum flooring, must follow the standard EN 12455.

#### O45 Wet room approval

Floor coverings marketed and sold for wet rooms are to be approved for their intended use in wet rooms according to the national industry standard:

- approved as a surface layer in wet rooms and/or
- approved as a waterproof barrier in wet rooms, (acting as a barrier behind ceramic materials and natural stone)

Installation instructions tailored to wet rooms are to accompany the flooring and be made available on the manufacturer's website.

- ☒ Approval according to national industry standards.
- ☒ Installation instructions that accompany the flooring and are available on the website.

### Background

The product information requirement remains unchanged from the previous version, since the requirement is judged to be relevant and fit for purpose. Wet rooms are rooms subjected to water or high relative humidity and are among the most critical rooms in a building, with any imperfections in the waterproofing posing a major risk of moisture damage to surrounding structures. Reliable construction solutions and professional performance are essential for problem-free and waterproof wet rooms.

Alongside industry rules on construction, performance and installation, there is an industry standard for approval of flooring materials and waterproof barriers. Wet room approval and approved labelling can be obtained once a product has been tested and judged to meet the requirements in the national industry standard for plastic flooring in wet rooms.

It is important that the fundamental requirements for wet room approval are fulfilled for flooring intended for use in wet rooms. A new requirement has therefore been introduced, such that plastic flooring marketed and sold for wet rooms is to be tested and approved according to national industry standards. These are stated, for example, in:

- Golvbranschens branschstandard för golvbeläggning av plast i våtutrymmen (The flooring industry standard for plastic flooring in wet rooms) (Sweden).
- Gulvfakta utgiven av Gulvbranchen (Flooring facts issued by the flooring industry) (Denmark).
- Anbefalt Våtromsprodukt från FFV – Fagrådet for Våtrom (Wet room products recommended by FFV – Expert Committee for Wet Rooms) (Norway).

The requirement also states that instructions for proper installation in wet rooms are to accompany the product and be available on the manufacturer's website.

## 4.9 Circular requirements

### O46 Labelling and traceability

Underlays, and floor coverings that are not glue down or that can be loose-lay installed, must be labelled with a batch code/production code and the name of the manufacturer or the name of the supplier. Marking systems, such as QR code and more advanced technologies may also be used.

- ☒ Picture or description of how the labelling is done and explanation on how the traceability between the license holder and the product is ensured.

### Background

As stated earlier in the criteria document, a way to drastically reduce the total environmental impact of a product is to reuse previous resources such as pre- or post-consumer recycled material. A way to guarantee access to known resources of good quality is if flooring manufacturers were able to close the materials loop by taking back their own damaged, or even, worn-out products. Furthermore, by taking back their own products, the producers can either further extend the floor lifespan (through repair) or, remove the most environmentally impactful scenarios from the end-of-use phase (landfill and incineration) if the whole product can be recycled and re-enter the manufacturing process.

There are however many challenges to overcome before a flooring manufacturer can claim to have a fully operational take-back system. The first step that needs to be taken is the one guaranteeing full traceability between the product and the manufacturer no matter where or when the flooring is installed. Both time and space parameters add some difficulty. Indeed, floor coverings are intended to have a long service life and can often change ownership especially in some area of use. Finally, there are many actors involved during the whole service life of a flooring and all of them must be informed to ensure that the installed flooring finds its way back to the right producer. The fact that some flooring must be glued down, because of higher safety and functionality requirements of some area of use, adds a technical challenge.

To increase the chance of product reuse or recycling of the materials included in the product, certain measures to ensure traceability between the floor covering/underlays and the manufacturer or license holder must be in place. Labelling renders Nordic Ecolabelled flooring more circular by increasing their chance to find their way back to their manufacturer, despite their long service life.

### O47 Warranty and Reparability

#### Warranty:

A warranty of at least 5 years must be provided with the purchase of a floor covering or flooring underlay.

The warranty must apply from the delivery date and must be communicated (see requirement O49). The warranty must be included in the product price.

*By warranty is meant an agreement between buyer and seller that goes beyond the legal guarantee and where the seller/manufacturer must offer to repair or replace parts that are damaged or not working properly. This warranty is provided without prejudice to the legal obligations of the manufacturer and seller under national law.*

### Reparability:

Underlays are exempted from points a) and b) in this requirement.

Information must be included in the consumer instructions or the manufacturer's website to be accessible to the users and installers.

- a) It must be possible to repair minor damage by, for instance, refurbishing/refinishing the top layer of the floor covering. A maintenance plan/schedule stating the different measures that can be taken over the years to prolong the service life of the floor covering must be provided with the purchase of a floor covering.
- b) Floor coverings that are not glued down, must be designed for disassembly in order to repair major damages and facilitate reuse, replacement, and recycling. Disassembly and replacement operations must possible of being carried out using common and basic manual or electrical tools.

Floor coverings that can be both installed as permanently glued down and in a floating/loose-lay fashion must fulfil both Reparability requirements a) and b).

Recommendation of keeping spare floor covering elements for possible event of repair and/or replace/re-install must be provided (See requirement O49).

- A copy of the warranty that indicates the terms and conditions of the extended product guarantee shown in the product information documentation and meeting the requirement must be provided (see example in Appendix 13).
- a) A description of a generic maintenance plan/schedule must be made available (see example in Appendix 14). The maintenance plan may be included in the maintenance instructions or any other document providing product information.
- b) A copy of the repair document or any other material where the information on design for repair must be provided. Simple and illustrated instructions regarding the disassembly and replacement of damaged elements must be provided.

### Background

For the purpose of undertaking repair and replacement of worn-out parts, the product must meet requirements on warranty and reparability.

A Nordic Swan Ecolabel product must have a good quality, and together with requirements related to durability, warranty is a factor that signals the product's lifetime and says something about what the customer can expect from the product. However, warranty should not be equated with longevity alone, which is affected by many factors, including how careful and often the product is used. A warranty is something that goes beyond the legal warranty and is an agreement between buyer and seller. The legal guarantee is regulated by law in contrast to a warranty. A warranty can be designed in many different ways, but Nordic Ecolabelling has set as a minimum requirement that it must go beyond the legal guarantee and that it must include replacement/repair if something breaks or does not work properly. It is not intended that marks from normal wear and tear should be covered by the warranty. It is important to emphasize that the warranty must cover more than what is covered by the legal guarantee.

The extended warranty of the products should be on the same basis of the mandatory limited guarantee in accordance with the national legislation. Information about the coverage must be indicated and is decided by the manufacturer. The warranty preferably contains information about who is

covered, what the consumers responsibilities under the warranties are, what the company will do if any of the covered events occur, what is not covered and what should the consumers do if they have a problem. The warranty may differ depending on the country of sales as it must follow individual national regulations and different warranty times may be provided depending on the product types and their different area of use. Warranty created according to recommendations/guidelines stated by national industry organisations may be assessed as sufficient documentation by the Nordic Ecolabel (see example in Appendix 13).

Requirements for warranty can stimulate manufacturers to make good quality products and choose suppliers who also supply high quality materials and parts. This is important for the product to have a long lifespan.

There are several ways to promote circularity. Processes having the most effects on reducing a product's overall environmental impact from the end-of-use phase tends to have very tight or short material loops. Indeed, processes such as product reuse, renovate and repair comprise few steps, have few stakeholders involved and do not require the use of a lot of resources (e.g., raw materials, energy or water). That is why, circular design, which is about designing a product so that parts can be replaced or so that the product can be more easily repaired/renovated, has been increasingly used by manufacturers.

In the case of flooring, it has been shown that extending their service life by renovation instead of buying new products (linoleum, plastic and wooden floors) leads from 79% up to 90% CO<sub>2</sub>-emission savings and from 90% up to 95% energy-savings depending on the product type.<sup>67</sup> Furthermore, the report including these results and written by IVL also mentions the lack of incentive actions from different stakeholders to promote refurbishment over purchasing of new floorings. Nordic Ecolabelling requires that a maintenance plan is offered with the purchase of floor covering. Example on how a rough maintenance plan/schedule could look like can be seen in Appendix 14. The maintenance plan can be included in other instruction documents such as the common "Care instructions".

Floorings that are installed in a floating/loose-lay fashion are usually made of individual components (plank or tiles) equipped with a click or an interlocking system that enables easy separation/disassembly and easy removal from the sub-floor. Nordic Ecolabelling requires a copy of the repair document or any other material with the information on design for repair for the floor covering.

Simple illustrations mean mainly sketches or rough drawings. If the consumer does not feel in the position to carry out the replacement, most of the companies that provide floor coverings have a customer service. Information on how to contact the customer service must be included. This requirement, as well as the requirement for warranty, the requirement for labelling and the requirement on product information enable to take into consideration all parameters needed to promote reuse/repair/renovate.

---

<sup>67</sup> <https://www.ivl.se/download/18.4c0101451756082fbad78/1603698658279/B2385.pdf>

## O48 Recyclability

To ensure material recycling, the following is required:

- a) The linoleum and plastic floor coverings manufacturers must offer that installation waste is material recycled. Installation waste must be recyclable.
  - b) For products other than wood floorings (solid wood, multi-layer wood and wood veneer), the manufacturer must have a technology enabling recycling of its own post-consumer material into new floor coverings, new flooring underlays or new products of equivalent value (downcycling is not allowed).
- a) Description of the processes to recycle post-installation waste.
- b) Documentation/flow-charts that show how the post-consumer material from worn-out product can be used in the manufacturing of new products. Nordic Ecolabelling assesses whether downcycling has occurred or not.

### Background

Circular economy does not only mean focus on closed resource loops for the individual product system. Joint circular resource systems may also be the solution. The Nordic Swan Ecolabel shares this approach. Hence, floor covering circularity can be steered by flooring manufacturers not only at the earlier stage of a product's life cycle, i.e., by designing/labelling/tracking, but also at the production phase and above all, at the end-of-use phase by actually taking back used floor coverings. The former can be addressed by having a plan to recover internally the waste generated during production (material recovery or energy recovery in the case of wood-based floorings). The latter implies to take the steps from producing repairable/recyclable products to actually repair/recycle these. Purchase returns, incorrect deliveries and faulty products can be send back and easily handled by the floor producers. However, it can be a challenge to develop a process to transform installation waste and worn-out products (or other post-consumer material) in new resource of sufficiently good quality so it can re-enter the manufacturing process and be part of new floorings or new flooring underlays again.

Floor manufacturers like Forbo, Unilin or Tarkett have already developed processes so that their own torn-out floorings or other post-consumer material can be used to make new floors or manufactured board. In this requirement, it is required that the manufacturers have developed a process enabling transformation of post-consumer material (their own worn-out products) so the obtained recycled material can be included in the production of either new floor coverings, new flooring underlays or other new products of equivalent value. For instance, the worn-out product can be grinded and be included in the back of a new product or, the wear layer of the worn-out product can be separated while the remaining layers can be reused in the manufacturing of a new product. The new product does not have to be Nordic Ecolabelled. Pilot projects showing recyclability of the product on a small-scale may be accepted. The collected worn-out products or the obtained post-consumer material may also be sold to other manufacturers that are then responsible for making new valuable products.

Nordic Ecolabelling requires that plastic and linoleum floor coverings manufacturers have developed a process to reuse/recycle installation waste as well as in some cases, post-consumer material (worn out products) to prove they

work with material efficiency and contribute to a more circular industry. The services must be communicated to the customer (O49 Product information). Solid wood, multi-layer wood and wood veneer have been exempted from the latter as the recycling possibilities for these products are limited and consequently the resulting environmental benefit as well (they contain much less fossil carbon compared to other product types).

Downcycling is not allowed, and it is up to Nordic Ecolabelling whether this has occurred after the recycling process or not. ISO standard 59004 “Circular Economy – Terminology, Principles and Guidance for Implementation” defines downcycling as recycling activities that obtain recovered resources with a lower value.<sup>68</sup> Downcycling can be defined more generally as the phenomenon of quality reduction of materials reprocessed from waste relative to their original quality. The reduced quality can express itself thermodynamically, functionally and economically, covering all perspectives of downcycling. Dilution, contamination (legacy chemicals), reduced demand for recycled materials, and design related issues can cause those downcycling effects.<sup>69</sup> Nordic Ecolabelling reckons that downcycling has occurred when, for instance, recycled materials from floor coverings or flooring underlays are used in less-demanding applications, such as single-use products (e.g., non-food-contact materials), or in products with lesser functional use (traffic cones, coaster, turf granulates, etc...). Downcycling has of course also occurred if the product’s only waste disposal alternative is energy recovery.

#### O49 Product information

*The Nordic Ecolabelled product must be sold with the relevant information on the packaging or any other documentation accompanying the product or on the manufacturer’s website and be accessible to the users and installers. Only the requirements associated with the specific type of product have to be fulfilled.*

Recommendations for the installation:

- Recommended upper limit for the subfloor’s relative humidity and temperature when laying the floor covering.
- Floating installation is recommended whenever possible. Reference must be made to the necessary preparation of the underlying surface, and the auxiliary materials needed. For instance, suitable type I Ecolabel Flooring underlays are to be recommended, if possible.
- If a glued down installation is recommended due to the possible longer duration, recommendation of using a type I Ecolabel adhesive/glue or a low emission adhesive complying with EMICODE EC1 or equivalent, if suitable, must be included. Method in case the flooring must be welded together.
- Illustrated assembly and disassembly instructions as stated in the requirement O46 Warranty and Reparability.

Recommendation for the surface treatment for uncoated floor coverings and floorings needing an oiled surface:

- Recommended type/quantity of oil or lacquer for oiled and untreated wood floorings so they can achieve their intended durability. See requirement Durability of floor coverings O43 for more information.

<sup>68</sup> <https://www.iso.org/obp/ui/#iso:std:iso:59004:dis:ed-1:v1:en>

<sup>69</sup> [https://www.researchgate.net/publication/360727530\\_A\\_terminology\\_for\\_downcycling](https://www.researchgate.net/publication/360727530_A_terminology_for_downcycling)

- Recommended finish products (e.g., oil, lacquer and other surface treatments) in case of flooring refurbishment. If there are suitable type I Ecolabel finish products or low emitting coating products in accordance with the Directive 2004/42/EC, these are to be recommended.
- Information about how the service life of the flooring can be extended through renovation e.g., sanding and surface treatment.

Recommendations for the use, cleaning and maintenance of the product.

- The flooring's areas of may be stated. See requirement Durability of floor coverings O43 for more information.
- Recommended cleaning method including cleaning products. If there are suitable type I Ecolabel cleaning products, these are to be recommended.
- Maintenance plan/schedule or instructions according to requirement Warranty and Reparability O46.

Information related to reparability:

- Recommended repair methods to restore the floor coverings after having suffered some damage (scratches, broken click, stain, etc...) according to requirement Warranty and Reparability O46.
- Information about the duration of the extended warranty. Recommendation of keeping spare floor covering elements for possible event of repair and/or replace/re-install must be written. See requirement Warranty and Reparability O46 for more information.
- Information on how to contact the customer service should be included in the document. The contact information refers to the phone, email address or even postal address of the license holder/flooring manufacturer.

Information related to end-of-use of the product:

- Instruction on how packaging waste must be sorted.
- Instruction on how the flooring/underlay must be handled or sorted when the customer wants to remove it.
- If there is a take-back system in place (for the product or the installation waste), the customer must have the possibility to reach the floor covering's manufacturer (e.g., via phone number or email address of the customer service) and use the system.

- ☒ Enclose a copy of the product information given to customers. All product information digitally accessible is also accepted (e.g., guide, instructions, manuals, links to diverse webpages).

## Background

Nordic Ecollabelling knows that the end-user also has steerability. They often have the will to do the right thing from an environmental perspective and that's why, they should be given the possibility to do so. Hence, flooring manufacturers need to inform them of what actions they can make to either, extend the service life of the product, or to dispose of it in the right manner when it is worn out.

This includes technical instructions and recommendations to ensure the good performance of the product, maintenance and cleaning instructions, repair manuals, general customer service information as well as sorting instructions. It is important that the customer is aware of the flooring manufacturer's sustainability work and service purchased with the floor covering. Extended warranty, possibility to repair/renovate through the creation of a maintenance schedule and possibility to use take-back systems must be clearly communicated.

## 4.10 Innovation

### O50 Innovation

The applicant/manufacturer must fulfil at least two (in total) of the following 21 innovations coupled to the four different areas in the table below:

Area	Requirement
Chemicals	Chemical products eligible or Nordic Swan Ecolabelling (e.g., adhesives and surface treatment products), used in the production of the Nordic Swan Ecolabel product are Nordic Swan Ecolabel.
	30% of the binder in the chemical product (e.g., adhesive or surface treatment) used in the production of the Nordic Swan Ecolabel product is made of renewable raw materials and fulfil requirements O14.
	None of the ingoing substances that are contained in the chemical products used in the production of the Nordic Swan Ecolabel product are classified as SVHC or CMR.
	For non-UV cured surface treatments: the quantity of environmentally harmful substances (classified as H410, H411 or H412), calculated in a wet state, applied in the surface treatment system is below than 40 g/m <sup>2</sup> .
	The concentrations of substances classified as CMR and/or environmental hazardous, in the final cured/hardened chemical product (such as acrylate monomers and photoinitiators in UV-cured chemical products) used in the production of the Nordic Swan Ecolabel product, is below 100 ppm according to analytical content tests (e.g., LC-MS, GC-MS) performed by a third party.
	The quantity of applied VOCs in the surface treatment system does not exceed 1g/m <sup>2</sup> .
	TVOC and SVOC values for the Nordic Ecolabel product are at least 50% lower than the thresholds given in requirement O41.
Raw materials and Biodiversity	100% by weight of the wood raw material, bamboo and cork used in the Nordic Swan Ecolabel product (production line) comes from forests that are managed in accordance with sustainable forestry management principles/recycled wood raw material as defined by FSC or PEFC and is covered by a valid Chain of Custody certificate in accordance with the FSC/PEFC schemes.
	Linoleum, laminate, plastic, hybrid floorings or underlays contain at least 20% pre- and/or post-consumer recycled material.
	All fillers used in plastic, linoleum floorings and underlays are sourced as pre- or post-consumer recycled material.
	None of the additives (added to materials, see requirement O20) used in the Nordic Ecolabel product are classified as environmentally hazardous according to CLP.
Climate	The action plan to optimize energy consumption/efficiency developed after the last energy audit has been fully implemented in accordance to recognized energy management system (all actions have been taken and changes made are already operational).
	Energy consumption for the manufacture of chemicals used in the construction of the final floor covering (e.g., adhesive, resin, filler and surface treatment) has been included in the energy consumption calculation.
	The E-score from the energy consumption requirement is at least: <ul style="list-style-type: none"> <li>- 14 for solid wood,</li> <li>- 13 for parquet flooring, laminate flooring, hybrid flooring, bamboo flooring and cork flooring,</li> <li>- 11 for linoleum flooring, plastic flooring and underlays.</li> </ul>
	The share of electricity produced from renewable energy sources (e.g., solar panels or its own wind turbine) and generated at the manufacturing site stands for at least 10% of the plant annual electricity consumption.
	100% of the purchased electricity is ecolabelled according to Bra Miljöval, EKO Energy or similar*.
Circular Economy	Floorings that need to be glued down are made fully traceable through the use of new technologies without affecting their recyclability.
	The solid wood or multilayer parquet is certified according to the FEP Parquet Refinishable Program administered by the European Parquet Federation (FEP). <sup>70</sup>

<sup>70</sup> [FEP is launching its Parquet Refinishable Program | Parquet.net](https://www.parquet.net)

	Manufacturer of wood floorings (solid wood, parquet or veneer) have developed a process to recycle/reuse these products and the new Nordic Ecolabel flooring contains at least 10% recycled/reused flooring material.
	The pre- and post-consumer recycled fractions used in the Nordic Ecolabel product are regularly tested for relevant SVHC and CMRs.
	The flooring manufacturer has a fully operational take-back system and new floorings (not necessarily Nordic Ecolabelled floorings) contain more than 10% of post-consumer recycled flooring material from reprocessed own products collected via the system.

*\* Ecolabels for electricity must follow Nordic Ecolabelling's guidelines for certification systems. Bra Miljöval-el/Good Environmental Choice and EKOEnergy follow the guidelines and are approved.*

- Documentation in relation to the above-mentioned alternatives in the requirement. The innovations shall be presented in line with the table above.

## Background

Nordic Ecolabelling sees this requirement as a mean to promote manufacturers who take innovative action and who strive in various ways to reduce the environmental impact of their products in the different life cycle's stages.

The innovations are categorised according to the 3 of the 4 pillars from the environmental platform developed by Nordic Ecolabelling. The four pillars are defined as the four different focus area the Nordic Ecolabelling is striving to write clear, concrete and meetable requirements on. These pillars are "Chemical", "Biodiversity", "Climate" and "Circular economy". For the product group floor covering, the pillar "Biodiversity" is difficultly applicable except when sourcing wood and other renewable raw materials. That is why, it was replaced by "Raw materials".

The floor covering industry is very committed to sustainability. For instance, flooring manufacturers, especially in the Nordic countries, have become a driving force to accelerate the shift from a linear economy to a more circular one. It seems logical to reward their commitment by giving them a hint on what Nordic Ecolabelling might look at in a near future. Two points must be fulfilled, and the manufacturer can decide which measure they wish to fulfil. This offers flexibility. If license holders wish to suggest additional innovation requirements, it is up to Nordic Ecolabelling to assess if they can be accepted and how they can be fulfilled.

## 5 Licence maintenance

The purpose of the licence maintenance is to ensure that fundamental quality assurance is dealt with appropriately.

### O51 Customer complaints

The licensee must guarantee that the quality of the Nordic Swan Ecolabelled product or service does not deteriorate during the validity period of the licence. Therefore, the licensee must keep an archive over customer complaints.

Note that the original routine must be in one Nordic language or in English.

- Upload your company's routine for handling and archiving customer complaints.

## Background

Nordic Ecolabelling requires that your company has implemented a customer complaint handling system. To document your company's customer complaint handling, you must upload your company's routine describing these activities. The routine should be dated and signed and will normally be part of your company's quality management system.

If your company does not have a routine for customer complaint handling, it is possible to upload a description of how your company perform these activities. During the on-site visit, Nordic Ecolabelling will check that the customer complaint handling is implemented in your company as described. The customer complaints archive will also be checked during the visit.

### O52 Traceability

The licensee must be able to trace the Nordic Swan Ecolabelled products in the production. A manufactured / sold product should be able to trace back to the occasion (time and date) and the location (specific factory) and, in relevant cases, also which machine / production line where it was produced. In addition, it should be possible to connect the product with the actual raw material used.

You can upload your company's routine or a description of the actions to ensure traceability in your company.

- ☒ Please upload your routine or a description.

## Background

Nordic Ecolabelling requires that your company has implemented a traceability system. To document your company's product traceability, you must upload your company's routine describing these activities. The routine should be dated and signed and will normally be part of your company's quality management system.

If your company does not have a routine for product traceability, it is possible to upload a description of how your company perform these activities. During the on-site visit, Nordic Ecolabelling will check that the product traceability is implemented in your company as described.

## 6 Changes compared to previous generation

- The criteria have been updated so that all requirements set on textile flooring have been removed and specific requirements have been updated or added to include flooring underlays.
- All substances classified as CMR, endocrine disruptor, regardless of the classification category, as well as PBT/vPvB and PMT/vPvM are now forbidden.
- Origin and traceability must now be documented for all raw materials, regardless of if they are virgin or recycled, as well as fossil-based or renewable.
- The product manufacturer must now have an energy consumption reduction and effectivization strategy.

- A new requirement set on product packaging recyclability has been implemented.
- Requirements on warranty, labelling and traceability, reparability and recyclability have been added to increase the products' circularity.
- A new concept of requirement called "Innovation requirements" has been added to reward license holders which have come further in their sustainability work regarding one particular area compared to other license holders or best-in-class on the market.

Below is a short list of the key changes compared with the previous version of the criteria:

Comparison between requirements from generation 7 with requirements from previous generation 6

Proposed requirement gen. 7	Req. gen. 6	Same req.	Change	New req.	Comment
O1 Description of the product and material composition	O1	X			The requirement has been rewritten.
O2 Description of the production chain and the manufacturing process	O1	X			The requirement has been rewritten.
O3 Overview of chemical products				X	New requirement to clarify chemical products used during the manufacturing process.
O4 Share of renewable/recycled raw materials	O2		X		The requirement has been tightened. The limit is still 70% and fillers may still be left out from the calculations again according to alternative c). However the factor promoting the use of renewable materials has been removed. Alternative b) has been tightened to promote the use of post-consumer material over pre-consumer material. The limit value is still of 60% but half of it must come from post-consumer recycled material.
O5 Chlorinated plastics in floor coverings and flooring underlays	O3	X			The background text has been updated.
O6 Nordic Swan Ecolabelled laminate and wood-based panels				X	Requirement added to facilitate application handling of laminate flooring.
O7 Tree species – restrictions	O4		X		The requirement has been updated with Nordic Ecolabelling's requirements concerning tree species that are prohibited or restricted. The limit value for PEFC/FSC certified wood fibre has been highered to 70%, with specific temporary exemption for oak parquet.
O8 Traceability and certification	O5		X		The manufacturer of the product is required to be CoC certified.
O9 Chemicals in reused wood and recycled material				X	New requirement for testing of chemicals in recycled wood raw material.
O10 Flax (linen), other bast fibres and linseed oil	O7	X			The requirement has been updated. The requirement has been adjusted so that it is clear it is also set on jute and linseed oil.

					The requirement is now called O10 Flax (linen), other bast fibres and linseed oil.
O11 Origin				X	Requirement added set on other raw material.
O12 Recycled fibres - test for harmful substances				X	Requirement added set on other raw material.
O13 Chemicals in recycled leather				X	Requirement added set on recycled leather.
O14 Raw materials for bio-based polymers				X	Requirement added set on renewable materials used in the production of polymers.
O15 Emission to water from production of foams	O16	X			The requirement has been updated.
O16 Blowing agents in foams	O18	X			The requirement has been updated.
O17 Rubber, synthetic latex (SBR) and natural latex	O17	X			The requirement has been updated.
O18 Recycled plastic, rubber and foam - Traceability				X	
O19 Chemicals in recycled plastic, rubber and foam	O14	X			Same requirement.
O20 Additives – prohibited substances				X	
O21 Recycled composite				X	
O22 Recycled composite - Additives – prohibited substances				X	
O23 Chemicals in recycled composite				X	
O24 Antibacterial substances	O24	X			The requirement has been updated.
O25 Classification of chemical products	O19	X			The requirement has been updated. The exemption for UV-curing products has been updated. The exemption for accelerators in linoleum has been removed.
O26 Classification of ingoing substances	O20		X		All CRM classifications are now prohibited. The exemption for the hardener in two components product has been reintroduced. An exemption for VAH in requirement 026 Classification of ingoing substances has been introduced and the requirement 030 volatile organic compounds has been updated
O27 Preservatives	O21	X			The requirement has been updated.
O28 Prohibited substances	O22		X		Some more substances and categories of substances are now forbidden.
O29 Nanomaterials	O25		X		The requirement has been updated. The exemption for modified SAS was reintroduced with a slight change to the wording. The exemption is now more specific and only "surface-treated pyrogenic

					silica” and the surface treatment must meet our chemical requirements.
O30 Volatile organic compounds	O23		X		The requirement has been updated. VAH may be added in 0,1% in adhesives and 1% in other chemical products. VAH in surface treatments is regulated in requirements O33/O34.
O31 Free formaldehyde				X	Additional requirement on formaldehyde to reduce emission from the products.
O32 Application method and quantity applied – surface treatment	O30	X			Same requirement.
O33 Environmentally harmful products and substances in surface treatment	O31	X			The requirement has been updated.
O34 Quantity of applied volatile organic compounds (VOC) in surface treatments	O32	X			The requirement has been simplified.
O35 Emissions to air from production of laminate				X	
O36 Polyurethane	O11		X		Requirement added set on products containing polyurethane.
O37 Energy mapping				X	It is now required that the manufacturer has performed an energy mapping and works according to an action plan.
O38 Energy consumption	O36		X		Multiple changes. The requirement has been adjusted and tightened. More processes are to be taken into account.
O39 Handling of waste and production waste	O37	X			The requirement has been updated.
O40 Packaging				X	
O41 Emissions from floor coverings and flooring underlays	O33		X		The requirement has been tightened. In addition, the accepted test methods have been updated regarding formaldehyde emission.
O42 Product performance – third-party verification				X	Requirement added for products not steered by harmonised standards. Appendix 12 has been simplified to only refer to the relevant standards.
O43 Quality and durability of floor coverings	O38		X		The requirement has been updated and made more comprehensive.
O44 Quality and durability of flooring underlays				X	
O45 Wet room approval	O40	X			Same requirement.
O46 Labelling and traceability				X	
O47 Warranty and Reparability				X	A 5 years-warranty must be given and is coupled to reparability. An appendix has been added to illustrate how an extended warranty can look like. The reparability requirement is set on both glued down and not glued down floor coverings.

O48 Recyclability				X	Linoleum and plastic floor coverings manufacturers must offer that installation waste is material recycled. The manufacturer (wood floorings are exempted) must be able to recycle its own worn-out products and use the post-consumer recycled material into new products. However, downcycling is not allowed.
O49 Product information	O39		X		The requirement has been updated and more information must be provided.
O50 Innovation				X	New concept of requirements.
O51 Customer complaints	Quality and regulatory requirements.	X			
O52 Traceability	Quality and regulatory requirements.	X			

## Appendix 1 Laboratories and methods for testing and analysis

### General requirements for test and analysis laboratories

Tests must be carried out in a correct and competent way. The analysis laboratory/test institute must be impartial and professional. If accreditation is not separately required, the test and/or analysis laboratory must comply with the general requirements of the EN ISO 17025 standard for the quality control of test and calibration laboratories or have official GLP status.

The applicant's own testing laboratory may be approved for analysis and testing if:

- the authorities monitor the sampling and analysis process, or if
- the manufacturer has a quality management system encompassing sampling and analysis and has been certified to ISO 9001 or ISO 9002, or if
- the manufacturer can demonstrate agreement between a first-time test conducted at the manufacturer's own laboratory and testing carried out in parallel at an independent test institute, and that the manufacturer takes samples according to a set sampling plan.

### Test method for COD emissions

COD content shall be tested in accordance with ISO 6060 (Water quality — Determination of the chemical oxygen demand) or equivalent. If another analysis method is used, the licensee must show that it is equivalent. An analysis of PCOD or BOD may also be used as verification if a correlation with COD can be demonstrated. The method for measuring TOC is ISO 8245 Guidelines for the determination of total organic carbon (TOC) and dissolved organic carbon (DOC).

Sample frequency: Emissions to water are calculated as the annual average value and are based on at least one representative daily sample per week. Alternatively, a sampling frequency set by the authorities may also be approved.

Sampling: Water samples must be taken after the process wastewater has been treated in any internal water treatment plant. The flow at the time of sampling must be indicated. If the process wastewater is externally purified with other wastewater, the analysis result should be reduced by the documented efficiency of the COD in the external water treatment plant. The analyses must be carried out on unfiltered and unsedimented samples in accordance with standard ISO 6060.

### Working environment – emissions to air

Air measurements must be carried out in accordance with standardised test methods in this area, such as EN 689 Workplace exposure – Measurement of exposure by inhalation to chemical agents – Strategy for testing compliance with occupational exposure limit values; EN 482 Workplace exposure – Procedures for the determination of the concentration of chemical agents – Basic performance requirements; or equivalent method approved by Nordic Ecolabelling. EN 14042 Workplace atmospheres – Guide for the application and use of procedures for the assessment of exposure to chemical and biological agents.

## Appendix 4      Directions for forestry certification

Nordic Ecolabelling sets requirements on the standards to which forestry is certified. These requirements are described below. Each individual national forestry standard and each certification system is reviewed by Nordic Ecolabelling as to fulfilment of the requirements. When a forestry standard is revised, it is re-reviewed.

### **Requirements on forestry standards**

The standard must balance economic, ecological and social interests and comply with the Rio Declaration's forestry principles, Agenda 21 and the Forest Principles, and respect relevant international conventions and agreements.

The standard must contain absolute requirements and promote and contribute towards sustainable forestry. Nordic Ecolabelling places special emphasis on the standard including effective requirements to protect the forest from illegal felling and that the requirements protect the biodiversity of the forest.

The standard must be available to the general public. The standard must have been developed in an open process in which stakeholders with ecological, economic and social interests have been invited to participate.

The requirements related to forestry standards are formulated as process requirements. The basis is that if stakeholders agree on the economic, social and environmental aspects of the forestry standard, this safeguards an acceptable requirement level.

If a forestry standard is developed or approved by stakeholders with ecological, economic and social interests, the standard may maintain an acceptable standard. Accordingly, Nordic Ecolabelling requires that the standard balances these three interests and that representatives from all three areas are invited to participate in development of the forestry standard.

The standard must set absolute requirements that must be fulfilled for the certification of the forestry. This ensures that the forest management fulfils an acceptable level regarding the environment. When Nordic Ecolabelling requires that the standard shall "promote and contribute towards sustainable forestry", the standard must be assessed and revised regularly to initiate process improvement and successively reduce environmental impact.

### **Requirements on certification system**

The certification system must be open, have significant national or international credibility and be able to verify that the requirements in the forestry standard are fulfilled.

### **Requirements on certification body**

The certification body must be independent, credible, and capable of verifying that the requirements of the standard have been fulfilled. The certification body must also be able to communicate the results and to facilitate the effective implementation of the standard.

The purpose of certification is to ensure that the requirements regarding forestry standards are fulfilled.

The certification system must be designed to verify that the requirements of the forest standard are fulfilled. The method used for certification must be repeatable and applicable to forestry. Certification must be in respect to a specific forestry standard. The forest must be inspected prior to certification.

### **Requirements on Chain of Custody (CoC) certification**

Chain of Custody certification must be issued by an accredited, competent third party (as for forest certification).

The system shall stipulate requirements regarding the chain of custody that assure traceability, documentation, and controls throughout the production chain.

If recycled fibre, wood shavings or sawdust are used, the pulp manufacturer must verify that this originates from recycled materials.

### **Requirements on organic production**

With regard to certified organic fibre raw material or production that is in the transition to organic production, the vegetable raw materials must be produced and checked in accordance with Council Regulation (EEC) No 2092/91 or 834/2007, or produced and checked in an equivalent way according to an equivalent regulatory system such as KRAV, SKAL, IMO or OCIA.

NB! Bamboo may either be certified according to a sustainable forestry standard or organic production.

### **Documentation**

Copy of forestry/ fibre raw material standard, name, address, and telephone number to the organization who has worked out the standard and audit reports.

References to persons who represent stakeholders with ecological, economic and social interests who have been invited to participate.

Nordic Ecolabelling may request further documents to examine whether the requirements of the forestry standard and certification system in question can be approved.

## Appendix 7, continuation:

### Calculation example for the sum of environmentally harmful substances (O33):

The manufacturer of flooring uses three products in the surface treatment system and roller coating technique is used (efficiency rate 95 %).

In surface treatment is used three products with following quantities:

Product A: applied with 10 g/m<sup>2</sup>

Product B: applied with 20 g/m<sup>2</sup>

Product C: applied with 10 g/m<sup>2</sup>

First, the environmental hazardousness is weighted for each surface treatment chemical product according to the weight equation in O33:

Product	Content of env.hazardous substances (%)			
	H410	H411	H412	= weighted env.hazardous content (%) calculated with formula 100*H410 + 10*H411 + H412
A	0	1	0	10
B	0	18	0,5	180,5
C	1	5	1	151

Thereafter the sum of the applied environmental hazardous substances in the surface treatment system is calculated using the above presented weighted content for each product (with consideration taken for the efficacy of the application method). Equation below is used:

$$\text{Applied quantity of respective product (g/m}^2\text{)} \times \frac{\text{Proportion of environmentally harmful substances in product (\%)}}{\text{Surface treatment efficacy (\%)}}$$

Hence:

Product	Applied quantity (g/m <sup>2</sup> )	Weighted env.hazardous content (%), see above	Applied amount env.hazardous substances (g/m <sup>2</sup> )
A	10	10	1
B	20	180,5	36,1
C	10	151	15,1
Total application of env. hazardous substances:			52,2 g/m <sup>2</sup>
Total application of env. hazardous substances (considering application method efficacy):			54,9 g/m <sup>2</sup>

The surface treatment system has therefore applied a weighted total sum env. hazardous substances of 54,9g/m<sup>2</sup> which fulfils the limit value of 60g/m<sup>2</sup>.

### Calculation example for applied sum of VOC (O34) in surface treatment systems:

The quantity of applied volatile organic compounds (VOC) is defined either by a) calculating the total content of volatile organic compounds (VOC), including

VAH, in surface treatment products or alternatively by b) using the equation in the requirement O34.

Alternative a):

Product	Applied quantity (g/m <sup>2</sup> )	VOC % in product	Applied VOC (g/m <sup>2</sup> )
A	48	2,42	1,16
B	26	5,39	1,40
C	52	3,86	2,01
Sum	126		4,57
Quantity of applied volatile organic compounds (VOC) total weight % = $4,57/126 = 3,63\%$			

The surface treatment system has therefore the total content of volatile organic compounds (VOC) by weight total of 3,63% which fulfils the limit value of 5 %.

Alternative b):

Product	Applied quantity (g/m <sup>2</sup> )	VOC % in product	Roller coating efficiency rate 95 %	Applied quantity (g/m <sup>2</sup> ) $\times \frac{\text{Proportion VOC in surface treatment (\%)}}{\text{Surface treatment efficacy (\%)}}$
A	10	0,12	0,95	1,26
B	20	0,01	0,95	0,21
C	10	0,04	0,95	0,42
Quantity of applied volatile organic compounds (VOC) total				1,89

The surface treatment system has therefore the quantity of applied volatile organic compounds (VOC) total of 1,89 g/m<sup>2</sup> which fulfils the limit value of 2 g/m<sup>2</sup>.

## Appendix 8 Declaration of energy consumption

floor coverings/flooring underlays manufacturer:
Name of product:

### Indicative list of activities that must be included and may not be included in the calculations of the energy consumption requirement:

Product type	Conditions for the electricity and fuel consumption (indicative list)	
	Included	Not included
Solid wood floorings	<ul style="list-style-type: none"> <li>— drying, grinding and sawing</li> <li>— sizing and trimming</li> <li>— sanding</li> <li>— coating</li> <li>— packaging</li> <li>— and any other activity needed for manufacturing</li> </ul>	<ul style="list-style-type: none"> <li>— activities occurring at the lumber mill (e.g., sawing, edging, trimming, drying and planing of the logs/lumber) and before such as felling and limbing.</li> <li>— manufacture of adhesives, lacquers or any other in-can preparation</li> <li>— manufacture of bought-out parts/layers that stands for less than 5 w% of the final floor covering (for instance, the manufacture of structural and decorative papers in laminate flooring is not to be included).</li> <li>— energy consumed in the quality control activities.</li> <li>— indirect electricity and fuel consumption (e.g., heating outside the manufacturing plant, lighting, internal/external transportation, etc.).</li> </ul>
Multi-layer wood floorings	<ul style="list-style-type: none"> <li>— drying, grinding and sawing</li> <li>— sizing and trimming</li> <li>— sanding</li> <li>— pressing</li> <li>— coating</li> <li>— packaging</li> <li>— and any other activity needed for manufacturing</li> </ul>	
Cork and cork tile floor coverings	<ul style="list-style-type: none"> <li>— drying, grinding and sawing</li> <li>— sizing and trimming</li> <li>— sanding</li> <li>— pressing</li> <li>— manufacturing of the core board if used in its structure</li> <li>— coating</li> <li>— packaging</li> <li>— and any other activity needed for manufacturing</li> </ul>	
Bamboo floor coverings		
Laminate floorings	<ul style="list-style-type: none"> <li>— manufacturing of the core board</li> <li>— impregnation process of the décor, overlay and backing paper</li> <li>— pressing</li> <li>— sizing</li> <li>— packaging</li> <li>— and any other activity needed for manufacturing</li> </ul>	
Linoleum flooring	<ul style="list-style-type: none"> <li>— oxidation to linoleum cement</li> <li>— mixing</li> <li>— calendaring</li> <li>— drying and curing</li> <li>— finishing</li> <li>— cutting</li> <li>— packaging</li> <li>— and any other activity needed for manufacturing</li> </ul>	
Plastic flooring	<ul style="list-style-type: none"> <li>— manufacturing of the binder(s)</li> <li>— extrusion</li> <li>— mixing</li> <li>— calendaring</li> <li>— finishing</li> </ul>	

	<ul style="list-style-type: none"> <li>— pressing/shaping and cutting</li> <li>— packaging</li> <li>— and any other activity needed for manufacturing</li> </ul>	
Others (e.g., multilayer Modular floor coverings, hybrid floorings)	<ul style="list-style-type: none"> <li>— manufacturing of the core board, binder or any main layer standing for more than 25 % of the final flooring</li> <li>— gluing/laminating/pressing the different elements together</li> <li>— sanding, coating and/or finishing</li> <li>— cutting and shaping</li> <li>— packaging</li> <li>— and any other activity needed for manufacturing</li> </ul>	
Underlays	<ul style="list-style-type: none"> <li>— manufacturing of the final product</li> </ul>	

Please declare the following energy data, based on annual average figures. Different delimitations for the energy consumption calculation are relevant for different floor types:

Declare the electricity consumption used in the production of the floor covering or flooring underlays [kWh/MJ] and declare how much renewable electricity is generated onsite (e.g., from solar panels, wind turbine and geothermal powerplant):

---

---

Declare the fuel consumption for each fuel type used in the production of the floor covering or flooring underlays [kWh/MJ]:

---

---

---

Declare, if relevant, an energy surplus [kWh/MJ], and declare the production quantity of the floor covering or flooring underlays [m<sup>2</sup>]:

---

---

Signature of floor covering/flooring underlay manufacturer

Date	Company
Signature by contact person	
Name of contact person	Phone

## Appendix 9 Energy content of fuel

The energy content of fuel is calculated based on the table below:

### Standard fuel values (1 kWh = 3.6 MJ):

Energy source/ Fuel type	Energy content FIN <sup>1)</sup> GJ/ton	Energy content SE <sup>2)</sup> GJ/ton	Energy content DK <sup>3)</sup> GJ/ton	Energy content NO <sup>4)</sup> GJ/ton	2012/27/EC Energy content* GJ
Petrol	44,3	43,7 (37,8 MJ/l)	43,8	43,9	44,0
Diesel	42,8	43,3 (35,3 MJ/l)	42,7	43,1	
LPG	46,2	46,0	46,0	46,1	45,2
Eo1 oil	42,8	40,6 (35,8 MJ/l, EO-1)	-	43,1	42,3
Eo5 oil	41,1 (sulphur<1 %)	43,1 (40,5 MJ/l, EO-5)	40,65 (fuel oil)	40,6	440,0
Natural gas	36,0 (GJ/1000 m <sup>3</sup> )	44,1 (GJ/1000 m <sup>3</sup> )	39,55 (GJ/1000 m <sup>3</sup> )	40,3 (GJ/1000 Sm <sup>3</sup> )	47,2
Power station coal	25,0	27,2	24,23	28,1	28,5
Pellets (7% W)	16,0	16,8	17,5	16,8	16,8
Peat	10,1 - 12,3	9,3 - 12,8 (50 % - 35 % W)	-	-	7,8 - 3,8
Straw (15% W)	13,5		14,5		
Biogas	23,0 (GJ/1000 m <sup>3</sup> )		23,0 (GJ/1000 m <sup>3</sup> )		
Wood chips (45% W)	10,5		9,3		13,8 (25 %W)
Waste wood	12,0	12,1 (30 % W)	14,7	16,25 - 18 (dry)	

\* Energy efficiency directive, 2012/27/EC, Annex IV, «Energy content of selected fuels for end use».

1) Statistiska centralen i Finland, Fuel classification 2013.

2) Värmeforsk, Miljöfaktaboken 2011.

3) Energistyrelsen, Energy statistic 2012

4) Statistisk Centralbyrå. Notater Documents 30/2013. The Norwegian Emission Inventory 2013.

(% W) is the percentage by weight of water in the fuel and given the letter f in the formulas below. If nothing else is stated, f = 0% W and the ash content is average.

### Formula for calculating the energy content of woodchips<sup>71</sup>:

The energy content of woodchips depends on the water content. An example of how to calculate the energy content of woodchips is given below.

<sup>71</sup> Reference: Centre for Biomass Technology, c/o dk-TEKNIK (tel. +45 39 555 999): Videnblad fact sheet 125.2 (in Danish) first published 29 June 1998, revised 26 March 1999.

The energy content of dry wood is 19.0 MJ/kg.

Energy is required to evaporate the water in the wood. This energy reduces the heat value of the woodchips. The energy content can be calculated as:

$19.0 \text{ MJ/kg} - 21.442 * f / 100 = \text{MJ/kg}$ , where f is the water content in %W of the wood.

The factor "21.442" is the sum of water's heat of evaporation (2.442 MJ/kg) and the energy content of dry wood (19.0 MJ/kg).

If the applicant can refer to laboratory analyses of the heat value of a fuel, Nordic Ecolabelling may consider using this heat value for calculating the energy content.

## Appendix 10 Example of energy consumption calculation

A company produces laminate floorings and wants to apply for the Nordic Ecolabel. The company had installed PV panels several years ago, but additionally it buys gas and biomass every year to provide the production lines with electricity and heat. The consumption of fuels and electricity as well as the energy consumption and production of flooring for the last three years is summarized in the Table below:

### Electricity and fuel purchase, production and electricity generation of a company:

Year	Production floor (m <sup>2</sup> )	Electricity purchase (kWh)	Renewable electricity generated onsite (kWh)	Fuel purchase	
				Gas (kWh)	Wood chip (t, f=20%)
2020	1 780 685	10 399 200	1 559 880	753230	956
2021	1 856 956	11 036 987	1 655 548	775369	965
2022	1 653 269	9 856 321	1 478 448	725849	949
Average	1 763 637	10 430 836	1 564 625	751483	957

### Calculation of B:

The value for the B factor, the annual purchased electricity in kWh/m<sup>2</sup>, can be calculated from Table 2:  $B = 10430836/1763637 = 5,9 \text{ kWh/m}^2$ . Indeed, as stated in the requirement O33, the renewable electricity generated onsite is not to be included in the calculation of B. According to the calculation, the value for B is < **15 kWh/m<sup>2</sup>** and meets the requirement.

### Calculation of C:

The annual gas purchase in kWh/m<sup>2</sup> is:  $751483/1763637 = 0,43 \text{ kWh/m}^2$ . The annual wood chips purchase in kWh/m<sup>2</sup> is:  $(957000*14,7)/(3,6*1763637) = 2,22 \text{ kWh/m}^2$ . Indeed, according to Appendix 11 and the standard fuel value for wood chips with a moisture content of 20% is:  $19,0 - 21,442*20/100 = 14,7 \text{ MJ/kg}$ . The factor of 3,6 is present to convert the value from MJ to kWh. The sum of the fuel purchase in kWh/m<sup>2</sup> is the value to be used as C in the formula:  $C = 0,43 + 2,22 = 2,65 \text{ kWh/m}^2$ . According to the calculation, the value for C is < **15 kWh/m<sup>2</sup>** and meets the requirement.

### Calculation of A:

The share of renewable fuel purchased annually is:  $A = 2,22/(2,22 + 0,43) = 84\%$ . According to the calculation, the value for A is > **25%** and meets the requirement.

### Calculation of E:

Now that all factors have been calculated, E can be deducted:  $E = (84/20) + (5 - 5,9/3) + (5 - 2,65/3) = 4,2 + 3,0 + 4,1 = 11,3$ . According to the calculation, the value for E is > **10** (limit value for laminate flooring) and meets the requirement.

## Appendix 11 Standards for quality and durability testing of floor coverings

**Table 1 Standards to be used to test each floor covering type:**

Flooring type	Standards/Test method	Classification
Wood veneer floor covering	Flooring must comply with and be tested according to standard EN 14354.	EN ISO 10874
Factory lacquer solid and multilayer wood floorings	Flooring must comply with and be tested according to standard EN 13489. Thickness of the top layer Wood hardness of the surface layer must be tested. * Additionally, at least the following parameters must be tested: <ul style="list-style-type: none"> <li>- Elasticity of the lacquer according to EN 13696.</li> <li>- EN 13442 Resistance to chemical agents.</li> </ul>	EN 685 CTBA*
Factory oiled, uncoated solid wood and uncoated multilayer wood flooring	Flooring must comply with and be tested according to standard EN 13489. Thickness of the top layer Wood hardness of the surface layer must be tested. * Good maintenance instructions and maintenance advice to prolong the lifespan of the flooring must be made available to the customer (see requirement O49 product information).	
Cork tile floor coverings	Flooring must comply with and be tested according to standard EN 12104.	EN ISO 10874
Cork floor coverings	Flooring must comply with and be tested according to standard EN 16511. At least the following parameters must be tested: <ul style="list-style-type: none"> <li>- Wearing group according to EN 660-1 for wearing group</li> <li>- Effect of a castor chair according to EN 425</li> <li>- Resistance to furniture leg movement according to EN 425</li> <li>- Residual indentation according to ISO 24343-1.</li> </ul>	
Bamboo floor coverings	Flooring must comply with and be tested according to standard EN 17009 or EN 14354. At least the following parameters must be tested: <ul style="list-style-type: none"> <li>- Resistance to indentation according to EN 1534 EN</li> <li>- Elasticity of the lacquer according to EN 13696.</li> </ul>	– See table in requirement O43 for classification and limits.
Laminate flooring	Flooring must comply with and be tested according to standard EN 13329.	EN ISO 10874
Linoleum flooring	Flooring must comply with and be tested according to standard EN ISO 24011.	EN ISO 10874
Plastic flooring (PVC-free)	Flooring must comply with and be tested according to standard ISO 19322, EN 16776 or EN 14565.	EN ISO 10874
Others (e.g., multilayer Modular floor coverings, hybrid flooring)	Flooring must comply with and be tested according to standard EN 16511 or EN 17142.	EN ISO 10874

\* *CTBA Revêtements intérieurs Parquet 71.01*<sup>72</sup> (see appendix 12).

<sup>72</sup> <https://catalogue-bois-construction.fr/wp-content/uploads/2017/05/Performances-techniques-planchers-et-revetement-de-sol-int%C3%A9rieurs-1.pdf>

**Table 2 Class of use according to standard EN ISO 10874**

Area of use	Use class	Intensity level
Domestic (bedrooms, living rooms, entrance and corridors)	21	Moderate/light
	22	General/average
	22+	General
	23	Heavy
Commercial (hotels, offices, boutiques, schools, halls and department stores)	31	Moderate
	32	General
	33	Heavy
	34	Very heavy
Industrial (assembly, storage rooms and production halls)	41	Moderate
	42	General
	43	Heavy

## Appendix 12 Relevant information from standard EN 685 (translation from French)

Classification of wood hardness according to the tree/wood species, and correlations between the use classes in the EN 685 standard and the thickness of the top wear layer depending on the tree/wood species used is found in CTBA Revetments interiors Parquet 71.01.

In Europe, since 1996, the NF EN 685 (or EN ISO 10874) standard identifies classes of use for floor coverings. These classes are identified by number and/or symbol. The tens digit corresponds to the nature of the room: 2 = domestic, 3 = commercial and 4 = industrial. The number of units corresponds to the intensity of the traffic: 1 = moderate, 2 = general, 3 = high and 4 = very high.

In France, this classification has been adopted for parquet floors in the XP B 53-669 standard. As part of the revision of the XP B 53669 standard, a coherent set of characterization of the finish was introduced. Parquet floors not coated with a finish and with a top layer as indicated in the Table below are classified as the following:

### Correspondence between tree species hardness classes, minimum top layer thickness and floor coverings classes of use:

Tree species hardness classes	Class of unfinished parquet floors according to minimum top layer thickness (mm)			
	≥ 2,5	≥ 3,2	≥ 4,5	≥ 7
A <sup>1)</sup>	21	21	22	22
B <sup>2)</sup>	21	22	23	31
C <sup>3)</sup>	23	31	33	34
D <sup>4)</sup>	31	33	34	41

<sup>1)</sup> Class A corresponds to a hardness between 10 N/mm<sup>2</sup> and 20 N/mm<sup>2</sup>. Tree species in this class are notably and conventionally: *Alnus*, *Pinus sylvestris*, *Picea abies* and *Abies*.

<sup>2)</sup> Class B corresponds to a hardness between 20 N/mm<sup>2</sup> and 30 N/mm<sup>2</sup>. Tree species in this class are notably and conventionally: *Betula*, *Guarea cedrata*, *Larix decidua*, *Castanea sativa*, *Prunus avium*, *Pinus pinaster*, *Entandrophragma utile* and *Tectona grandis*.

<sup>3)</sup> Class C corresponds to a hardness between 30 N/mm<sup>2</sup> and 40 N/mm<sup>2</sup>. Tree species in this class are notably and conventionally: *Pericopsis elata*, *Dicorynia guianensis*, *Carpinus*, *Quercus*, *Acer*, *Eucalyptus*, *Fraxinus*, *Fagus*, *Chlorophora excelsa*, *Tieghemella heckelii*, *Baillonella toxisperma*, *Distemonanthus benthamianus*, *Juglans L.*, and *Ulmus*.

<sup>4)</sup> Class D corresponds to a hardness greater than 40 N/mm<sup>2</sup>. Tree species in this class are in particular and conventionally: *Azelia*, *Myrocarpus fastigiatus*, *Handroanthus*, *Hymenaea*, *Intsia* and *Millettia laurentii*.

## Appendix 13 Example of extended product warranty

The extension of the product warranty must be free of cost and under the same conditions of the legal one.

### **Example of clauses to be included in the extended warranty (requirement O46)**

#### **Extended warranty**

##### **1. Who is covered?**

The extended warranty is given only to the original retail purchaser of the product and is our warranties.

##### **2. What are you responsible for under extended warranties?**

To be covered under the extended warrant, the consumer needs to retain the sales slip and make sure that the flooring is properly installed in accordance with the installation instruction provided with the flooring. The consumer must also properly care for the new flooring following the maintenance instructions that are provided with the flooring.

##### **3. What is not covered by the extended warranties?**

The extended warranties do not cover conditions caused by improper use or maintenance, such as a) reduction in gloss, marks, scuffs, scratches, gouges, dents or cuts, including those caused by pets, b) damaged caused by negligence, accidents, misuse or abuse (e.g., dragging object across the floor without proper protection), c) wear caused by pebbles, sand or abrasives...

##### **4. What should the customer do if s/he has a problem?**

Contact either of the company or the retailers they have agreement with.

##### **5. Other issues**

The number of years that the extended warranty covers should be indicated. The number of years should exceed five years and depends on the type of floor covering and finish. E.g., residential finish engineered wooden floor coverings can vary between 50 and 15 years depending on the wood used as raw material and the finished applied. Solid wooden floor coverings can be twice and even three types sanding. If done by professionals, this can extend the life of the floorings.

## Appendix 14 Example of maintenance schedule

### Example of a maintenance plan/schedule for requirement O47

Condition	Action	Incidence for Domestic use	Incidence for Commercial use	Incidence for Highest traffic
<ul style="list-style-type: none"> <li>- Loose dirt</li> <li>- Bonded dirt</li> <li>- Care</li> </ul>	Refresh (follow the maintenance and care instructions provided with the floor covering).	<ul style="list-style-type: none"> <li>- 1-2 times a week</li> <li>- Weekly</li> <li>- Bi-monthly</li> </ul>	<ul style="list-style-type: none"> <li>- 3-5 times a week</li> <li>- Weekly</li> <li>- Monthly</li> </ul>	<ul style="list-style-type: none"> <li>- Daily</li> <li>- 2 times a week</li> <li>- Weekly</li> </ul>
Stubborn stains	Revive (follow the maintenance and care instructions provided with the floor covering). Contact the flooring manufacturer if necessary.	Once a year	3-4 times a year	4-6 times a year
Scratches	Contact the flooring manufacturer to plan maintenance. Recoat is recommended or, Repair (use wax or filler) or Replace the affected part.	Usually after 5-10 years	Usually after 3-5 years	Usually after 2-3 years
Worn	Contact the flooring manufacturer to plan more extensive maintenance. Renew the surface coating or Repair/Replace the broken part is recommended or, Replace the flooring.	Usually after 10 years	Usually after 5 years	Usually after 3 years
